

The SAGE Encyclopedia of

CRIMINAL PSYCHOLOGY

Robert D. Morgan
Editor

1

About the pagination of this eBook

This eBook contains a multi-volume set.

To navigate the front matter of this eBook by page number, you will need to use the volume number and the page number, separated by a hyphen.

For example, to go to page v of volume 1, type "1-v" in the Go box at the bottom of the screen and click "Go."

To go to page v of volume 2, type "2-v"... and so forth.

About the Editor

Robert D. Morgan is the John G. Skelton Jr. Regents Endowed Professor in Psychology, chairperson for the department of Psychological Sciences, and director of the Institute for Forensic Science at Texas Tech University. He completed a BS degree in psychology from the University of Nebraska at Kearney in 1991, an MS degree in clinical psychology from Fort Hays State University (Kansas) in 1993, and a PhD in counseling psychology from Oklahoma State University in 1999. He completed a predoctoral internship at the Federal Correctional Institution–Petersburg (FCI–Petersburg, Virginia) in 1998–1999, and a postdoctoral fellowship in forensic psychology at the Department of Psychiatry, University of Missouri–Kansas City School of Medicine and Missouri Department of Mental Health in 1999–2000.

Dr. Morgan’s research and scholarly activities include treatment and assessment of justice-involved persons with mental illness, effects of incarceration including in restricted housing units, and forensic mental health assessment. His

research has been funded by the National Institute of Mental Health, the National Institute of Justice, and the Center for Behavioral Health Services & Criminal Justice Research. He has authored or coauthored over 95 peer-reviewed articles and book chapters, and he has authored or edited four books including *A Treatment Program for Justice Involved Persons With Mental Illness: Changing Lives and Changing Outcomes* and *A Clinician’s Guide to Violence Risk Assessment*. In addition, he codeveloped a treatment program for inmates placed in segregated housing units (i.e., *Stepping Up and Stepping Out: A Mental Health Treatment Program for Inmates Detained in Restrictive Housing* to be published by Routledge Press).

He has over 20 years of experience in correctional and forensic psychology, he has completed approximately 1,000 criminal pretrial mental health evaluations and posttrial criminal risk assessments to include issues of competency to stand trial, criminal responsibility, and criminal risk, and he consults with state and private correctional agencies to inform practice.

About the Associate Editors

Mark E. Olver, PhD, RD Psych, is a professor and registered doctoral psychologist at the University of Saskatchewan, in Saskatoon, Saskatchewan, Canada, where he is involved in program administration, graduate and undergraduate teaching, research, and clinical training. Prior to his academic appointment, Mark worked as a clinical psychologist in various capacities, including providing assessment, treatment, and consultation services to young offenders in the Saskatoon Health Region and with adult federal offenders in the Correctional Service of Canada. He currently supervises a clinical placement that involves training psychology graduate students on conducting forensic psychological assessments with federally sentenced men. He has published over 100 journal articles and book chapters and his research interests include offender risk assessment and treatment, young offenders, psychopathy, and the evaluation of therapeutic change. Mark is the action editor for the journals *Sexual Abuse* and *Criminal Justice and Behavior* and was recently appointed as a Fellow of the Association for the Treatment of Sexual Abusers. He is codeveloper of the Violence Risk Scale–Sexual Offense version (VRS-SO) and Violence Risk Scale–Youth Sexual Offense Version (VRS-YSO), two sexual violence risk assessment and treatment planning tools, and he provides training and consultation services internationally in the assessment and treatment of sexual, violent, and psychopathic offenders. Mark is an avid runner and guitar player—he may be found doing either of these when he is not somewhere sitting in front of a computer.

Keira C. Stockdale obtained a PhD in clinical psychology from the University of Saskatchewan in

2008. Her doctoral research involved a psychometric evaluation of a violence risk assessment and treatment planning tool for youth: the Violence Risk Scale–Youth Version. Keira’s clinical experiences have included the provision of assessment and treatment services to violent and high-risk adult and young offenders in both institutional and community settings. She is a registered doctoral psychologist with the Saskatchewan College of Psychologists and practices in Saskatoon, Saskatchewan, Canada.

Keira is currently employed with the Saskatoon Police Service with a mandate to provide clinical and behavioral science knowledge/expertise to the design, implementation, and evaluation of police and integrated community practices with the goal of increasing community safety. As part of this role, she supervises psychology residents working with a specialized team of police and community partners (e.g., probation, prosecutions, justice community support workers) providing integrated risk management/reduction services to high risk, violent offenders in the community.

Keira is an adjunct professor in the Department of Psychology at the University of Saskatchewan where she has served as a sessional lecturer and is involved in doctoral student research. She is also involved with a newly established police analytics lab (Saskatchewan Police Predictive Analytics Lab or SPPAL) and is currently working with university, government, and police partners on an inaugural SPPAL initiative focusing on missing persons. When not working on these initiatives, Keira is a long-standing true-crime junkie, mindfulness mediation aficionado, and Pilates enthusiast.

Introduction

Crime and response to crime elicit fear, anger, intrigue, and curiosity while serving as a focal point for social, professional, and political discussions worldwide. One only need to turn on the evening news or review highly rated television shows such as *Law & Order*, *FBI*, *CSI*, and other crime and law shows that frequent the airwaves to observe the prominence of crime in U.S. culture. Crime is interesting. It is also harmful and costly in terms of fiscal as well as physical and emotional costs.

Given the proliferation of crime, it behooves us as a society to understand criminal behavior and responses to crime. Psychology, the science of behavior, offers one scientific lens from which to view and understand crime. Psychology is rooted in the scientific method, and thus, the psychology of crime is also scientifically grounded.

The psychology of crime must span the criminal enterprise from the commission of crime, to the apprehension of a criminal, to the legal process, to the sentencing, sanctioning, treatment, and community reentry of those convicted of crime. An encyclopedia on crime and psychology must include perspectives on the criminal, but also victims, practitioners (e.g., law enforcement officers, judges, attorneys, health professionals, mental health professionals, correctional officers, probation officers), researchers and scholars, and policy makers alike. All of society is impacted by crime, and, thus, *The SAGE Encyclopedia of Criminal Psychology* must be holistic in topical coverage.

That is the aim of this encyclopedia, to take readers through the entire landscape of crime from the act, to the impact on victims (and society), to suspect identification and arrest, to legal adjudication, to sentencing, sanctioning, treatment and rehabilitation, and community reentry, and hopefully concluding with desistance from further crime—all from a psychological perspective. This resource is intended to inform and educate students,

laypersons, clinicians, scholars, and policy makers alike as we strive as a collective society to reduce not only the incidence but also the harms of crime.

Organization and Content of the Encyclopedia of Criminal Psychology

The SAGE Encyclopedia of Criminal Psychology is a broad, interdisciplinary reference work aimed at students, laypersons, and professionals interested in the intersection of clinical psychology, forensic psychology, social psychology, and criminology. My aim was to provide a state-of-the-art survey of the field of criminal psychology and address questions that span the criminal justice spectrum including intriguing questions such as *What are some of the theories behind criminal behavior? What tools do forensic psychologists employ to help prevent repeat offending? How does early childhood maltreatment contribute to criminal behavior? Does imprisonment contribute to mental illness?* This encyclopedia looks at crime, criminal behavior, and criminal justice processes primarily through the lens of psychology, presenting up-to-the-minute research and ready-to-use facts, sorting out findings on the psychological roots of criminal behavior and their social implications. To accomplish this, I recruited the top researchers and clinicians across multiple fields—psychology, criminology, social work, and sociology—to contribute to the 512 entries.

The entries included in *The SAGE Encyclopedia of Criminal Psychology* are listed in alphabetical order but are organized around 13 categories, as presented in the Reader's Guide. These categories aimed to provide coverage of the process of crime from criminal intent and action, to arrest and adjudication, to sanctions and interventions, and to community reentry. In addition, those working in criminal justice and who review global perspectives

on crime and psychology are included where possible. These 13 thematic categories include the following:

- Biases in Crime Policies and Prevention
- Crime Policies
- Criminal Justice Legal Processes
- International Perspectives
- Offender Assessment
 - Criminal Risk Assessment and Recidivism Prediction
 - Forensic Assessment
 - Mental Health Assessment
 - Offender Risk Assessment and Risk Level Classification
 - Protective Factors Assessment
 - Suicide and Self-Harm Risk Assessment
- Offender-Crime Theories and Typologies
 - Criminal Organizations and Networks
 - Cybercrime
 - Female Offenders
 - Juvenile Offenders
 - Occupational and Corporate Crime
 - Offenders With Mental Illness
 - Property Offenders
 - Psychopathy
 - Sexual Offenders
 - Substance-Abusing Offenders
 - Violent Offenders
- Preparing for a Criminal Justice Career
- Prison Services and Treatment
- Prisons and Prisoners
- Rehabilitation and Reentry
- Research in Criminal Psychology
- State, Federal, and Private Criminal Justice Agencies
- Theories of Crime

Developing the Encyclopedia

After developing these 13 categories, members of the editorial board, my associate editors, and I developed a list of all crime and psychology topics we could think of and I assigned these topics to appropriate thematic categories. It was our mission to develop an exhaustive list of content relevant to crime and psychology, and these topical categories guided our thought process. Each entry included in this encyclopedia is categorized into one or more of these 13 thematic categories.

Once categories were identified, I developed a list of potential contributors from personal and professional contacts, recommendations by my associate editors and editorial board, and by scouring scientific, professional, and popular media literature to identify potential contributors. This process ensured that all contributors were recognized experts in the content of their entries, resulting in entries written by eminent content experts.

Contributors were asked to write entries to appeal and to educate as broad an audience as possible, with a target audience of high school and college/university students (to include both undergraduate and early graduate) within departments and programs of psychology, counseling and human services, social work, forensics, sociology, criminology, criminal justice, law, and political science. Laypersons and paraprofessionals with interests or work at the intersection of crime and psychology were also included in our target audience. To provide readers comprehensive coverage of the topic, contributors were instructed not only to provide a review of the topic but also to include a list of recommended readings and to refer readers to other related entries in this encyclopedia.

Upon receipt of entries, members of the editorial board, associate editors, and/or I reviewed the entry to ensure accurate and comprehensive coverage of topics. I define accuracy here as providing all relevant information of a topic and not limiting coverage to one's professional perspective. After the entry was accepted by my team, the entry was forwarded to Carole Maurer, developmental editor for this encyclopedia. Ms. Maurer provided invaluable edits and additional content guidance where appropriate. Ms. Maurer and her team reviewed and approved every entry before the entry was submitted for copy editing and eventual publication.

As a result of this process, each entry was developed by an expert (frequently the eminent expert on the topic), reviewed by content and editorial experts, and subsequently published to form an encyclopedia that is broad yet comprehensive in its coverage of crime and psychology content. It is my hope that you will find *The SAGE Encyclopedia of Criminal Psychology* to be a rich and valuable resource for you, your students, staff, clients, and colleagues.

Acknowledgments

There are many people to acknowledge and thank for a project of this magnitude to be successful. First, I thank Maureen Adams, acquisition editor at SAGE who dreamed up this project and entrusted me to guide it to the finish line. Next, I thank Sue Moskowitz and Leticia Gutierrez for helping coordinate authors and author entries as their uncanny organizational abilities kept this project afloat. I am most indebted to and grateful for Carole Maurer, content development supervisor, SAGE Publishing, without whose encouragement, guidance, expertise, and most importantly gentle persistence this project would still not be completed.

I thank my graduate students Travis Brace, Briann Olafsson, Faith Scanlon, and Stephanie Van Horn who helped scour the scientific and popular press literature to identify potential contributors for entries. I'm also grateful to Faith and Stephanie for assisting me in reviewing entries. I thank and acknowledge the significant contribution of my editorial board, including Robert K. Ax, Midlothian, Virginia; Amy Blank-Wilson, University of North Carolina; Jennifer Eno Loudon, University of Texas at El Paso; Matthew Epperson, University of Chicago; and Jeremy F. Mills, Carleton University, for their commitment and energy when recommending

potential contributors and especially for reviewing entries. I am especially grateful (and indebted) for the contributions of my associate editors, Mark Olver, University of Saskatchewan, and Keira Stockdale, Saskatoon Police Service. Drs. Olver and Stockdale were instrumental in developing content areas, recommending contributors, and tirelessly reviewing entries. This encyclopedia is thorough and comprehensive in large part due to their contributions.

I thank the contributors for their entries as well as for their commitment and passion for the field of criminal psychology. Without you, this project would not have been possible.

I also acknowledge the significant contribution of Texas Tech University, which has provided continued support of my professional efforts throughout my career to include time required for this project. Finally, I acknowledge the contributions (and sacrifices) of my family, who remain a constant source of support. I am particularly grateful for my wife, Stacy, who holds down the fort when I'm traveling for my various criminal justice pursuits, and who is always by my side with encouragement and support no matter how many projects I take on. This encyclopedia was a big one, so as always, thank you, Stacy, for helping me manage and stay sane to the end!

Robert D. Morgan

Sara Miller McCune founded SAGE Publishing in 1965 to support the dissemination of usable knowledge and educate a global community. SAGE publishes more than 1000 journals and over 800 new books each year, spanning a wide range of subject areas. Our growing selection of library products includes archives, data, case studies and video. SAGE remains majority owned by our founder and after her lifetime will become owned by a charitable trust that secures the company's continued independence.

ACADEMIC DISCIPLINES

An academic discipline can be defined as a field of study. Usually an academic discipline focuses on one area of knowledge, studied at a university or higher education institution. An academic discipline is comprised of many working pieces, such as intellectual experts who may educate others, issues and inquiries within the discipline leading to research, and application of knowledge to real-world settings. There are a number of academic disciplines connected to the field of criminal psychology. It is important to have an understanding of the various academic disciplines associated with criminal psychology, as it is an interdisciplinary field. Often, experts in different academic disciplines collaborate on research and applied work in criminal psychology. This entry describes academic disciplines associated with the field of criminal psychology. Each description includes a brief definition of the academic discipline, information on the origin of the discipline, and how the discipline is related to criminal psychology.

Many of the academic disciplines affiliated with criminal psychology fall under the larger category of social sciences and humanities. Disciplines within the social sciences and humanities category include psychology, sociology, criminology, anthropology, philosophy, history, political science, and economics. Academic disciplines such as geography and law are also related to criminal psychology. Most academic disciplines have both an applied and experimental side and often a

complex combination of the two. The experimental side is concerned with conducting research to gain knowledge. The applied side focuses on applying knowledge to real-world settings.

Psychology

Psychology can be broadly defined as the scientific study of the human mind, including both behavioral and mental processes. Although psychology can fall within the social science and humanities category, it is increasingly classified as a science, technology, engineering, and mathematics discipline. Psychology is a highly scientific discipline with both qualitative and quantitative aspects. It emerged from the field of philosophy, as early philosophers began to create theories about the workings of the mind. True experimental psychology emerged in the 18th century. As the psychology discipline grew, it branched off into more specialized academic subdisciplines, such as social psychology, forensic psychology, correctional psychology, clinical psychology, cognitive psychology, developmental psychology, community psychology, abnormal psychology, and counseling psychology. There are also additional subdisciplines of psychology. All of the aforementioned subdisciplines of psychology have something to contribute to criminal psychology.

Social Psychology

The subdiscipline of social psychology examines human behavior and mental processes within

the interpersonal context of social situations. This includes the effects of other people, real or imagined, on human thoughts, behaviors, and emotions. Areas of research in social psychology include aggression, perception of self and others, attitudes, persuasion, leadership, group dynamics, helping behavior, social cognition, prejudice, conformity, and obedience to authority.

Forensic Psychology

Forensic psychology is a wide-ranging subdiscipline concerned with the intersection of psychology and the legal system. Traditionally, forensic psychology referred specifically to the clinical application of psychology in legal settings. Forensic psychology was originally synonymous with the broad-based study and application of all areas within psychology and law, including both the clinical and experimental areas. In 2001, forensic psychology was recognized by the American Psychological Association as its own subdiscipline of psychology. Forensic psychology includes topics such as psychological assessment and treatment of criminal offenders, risk assessment, police psychology, eyewitness testimony, police interrogations and confessions, domestic violence, sexual offending, jury decision-making, legal rights, children in the legal system, violent offences, deception, and the impact of crime on victims.

Correctional Psychology

Correctional psychology is an academic subdiscipline that encompasses the use of psychology within correctional settings. Prisons, jails, and juvenile detention centers are all considered correctional settings. Correctional psychologists are interested in persons who were, or are currently, offenders. Within correctional psychology, there is an emphasis on the assessment and rehabilitation of offenders, including their reentry into the community.

Clinical Psychology

The subdiscipline of clinical psychology focuses on the evaluation, diagnosis, and treatment of individuals with psychological issues. Psychological issues can include impairments or

disabilities, dysfunctional mental processes, and dysfunctional behaviors.

Cognitive Psychology

Cognitive psychology is a subdiscipline of psychology interested in the structures of the human brain and their connection to mental processes and behavior. Specifically, cognitive psychology is concerned with topics such as memory, motor abilities, thinking and reasoning, attention, the use and comprehension of language, and perception.

Developmental Psychology

Developmental psychology focuses on the ways in which behavior and mental processes develop, or change, over the life span. Developmental psychology includes the study of child development, from infants to adolescents, as well as adult development. Developmental psychology is concerned with a range of psychological processes, and often ties in with other subdisciplines of psychology, such as social and cognitive psychology. Topics covered in developmental psychology include personality, motor abilities as connected to brain functioning, morality and judgment, and issues of the self as an identity.

Community Psychology

The academic subdiscipline of community psychology focuses on individuals within communities. Community psychology is similar to social psychology; however, the scope of knowledge is generally narrower, with an emphasis on the fit of a person within their respective community.

Abnormal Psychology

Abnormal psychology is interested in the evaluation and treatment of persons who deviate from normal psychological functioning. Abnormal psychology generally focuses on mental disorders in relation to personality, thoughts, and emotions but also includes other forms of deviant behavior.

Counseling Psychology

Counseling psychology is a subdiscipline of psychology that focuses on techniques used to

provide treatment for psychological or developmental issues. Various forms of therapy are tested and applied in counseling psychology to find out which treatments should be used. There are different forms of counseling psychology, where counselors may work with individuals, couples, or families.

Sociology

Sociology is the study of society and the social activity of humans. Although sociology is closely related to psychology, there are some distinctions that separate them as academic disciplines. Sociology is generally focused on group behavior, whereas psychology focuses on individuals. Sociology is concerned with the role of society and what influences social relationships. Concepts of gender, religion, ethnicity, culture, and socioeconomic status are studied in terms of their influence on society. Sociology examines how institutions, organizations, and networks originate and develop over time. Sociology can be traced as far back to the thinking of the early Greek philosopher, Plato; however, some believe sociology originated in the 14th century. Sociology is associated with criminal psychology as crime has a direct impact on society, and many of the social aspects of sociology have an impact on criminal behavior.

Criminology

The academic discipline of criminology is interested in crime. Specifically, criminology is the study of criminal behavior, management or control of crime, causes and implications of crime, types of crime, and methods to prevent crime. Criminology has a multidisciplinary history and originally was designed to be an intersection of sociology, anthropology, psychology, social work, economics, law, and policing. Criminology has been studied since the 18th century. It is closely linked to criminal psychology as both disciplines consider the causes and consequences of crime, on both individuals and society.

Anthropology

Anthropology is the study of human beings, from our origins to the present day. Anthropologists are

interested in human culture as well as the physical and biological development of the human race. The concept of anthropology originated in the 15th century. As an academic discipline, however, anthropology expanded in the late 18th century when many organizations focused on studying anthropology emerged. The academic discipline of anthropology is relevant to criminal psychology as anthropologists are often experts on human anatomy as well on human social and cultural practices. Forensic anthropology is a subdiscipline of anthropology that is particularly relevant to criminal psychology; for example, forensic anthropologists are often asked to examine human remains at crime scenes.

Philosophy

Philosophy is a broad field of study concerned with understanding, and theorizing about, a wide range of topics. Concepts such as perception, reality, human existence and purpose, functioning of the mind, morals and values, reasoning, creativity, wisdom, and language are all relevant to the field of philosophy. Philosophy is one of the oldest academic disciplines, and its history is often divided and described by either western or eastern origins. Philosophy is connected to criminal psychology as many modern concepts about criminal psychology have origins in early studies of philosophy.

History

The academic discipline of history is concerned with the study of the past. The term *history* was coined in ancient Greece. The field incorporates subdisciplines, which focus on specific areas of interest, such as environmental history or economic history. History is associated to criminal psychology in that historians sometimes examine criminal behavior during some past time period. History of a specific individual, such as their development and events in their life, can be connected to their criminality.

Political Science

The academic discipline of political science is considered a social science. Studies of political science centralize around the role of social governments,

and their respective political institutions, actions, ideas, and behaviors. As governments vary widely in their policies and ideals across the world, political science focuses on how governments operate and interact with one another. Generally, policies created by governments are closely linked to social laws. As criminal psychology is interested in legal issues and breaking of laws, it is important to understand how these laws are managed and interrelated with politics.

Economics

Economics is an academic discipline that is concerned with the management of goods and services. This includes manufacturing, distribution, utilization, and consumption. The first theories of economics can be dated back to early civilizations. Goods and services generally have a cost and are traded either for one another or for monetary value. The academic discipline of economics is related to criminal psychology as crime frequently involves goods and services. Additionally, the socioeconomic status of an individual or place may influence the frequency and types of crime.

Geography

Geography is an academic discipline involving the surface of the Earth and its inhabitants. Geography focuses on the structure, pattern, and spatial distribution of landmasses. Maps have been dated back to the 9th century. The academic discipline of geography is related to criminal psychology as criminals are often studied based on their geographic location or spatial distribution of criminal acts. Geography can be used to help create a criminal profile of a suspect and to pinpoint where crimes have occurred and where future crimes might take place.

Law

The academic discipline of law focuses on the study and application of the system of rules designed to regulate society. Law varies across the world according to the rules and regulations defined by countries, states, and social institutions. The rule of law has been noted in early societies, as early as 3000 BCE in records from

ancient Egyptians. The academic discipline of law is closely related to criminal psychology as they directly influence each other. Laws govern individuals and societies and can have a significant impact on criminal psychology, including defining which behaviors are considered criminal. Social sciences, especially criminal psychology, examine the impact of laws on human behavior. Research can also influence and shape law, as laws may be modified as a result of research conducted by criminal psychologists. Generally, the subdiscipline of criminal law is most closely associated to criminal psychology.

ACADEMIC PROGRAMS FOR PRISONERS

Academic programs provided in adult and juvenile correctional facilities are designed to develop the knowledge and skills inmates need for success after release, focusing on instruction that leads to high school, career and technical, and postsecondary education credentials. These programs are widely considered to be a centerpiece of inmate rehabilitation efforts, often complementing other programs focused on life and vocational skills and those designed to reduce drug and alcohol

dependency, improve interpersonal relationships, gain financial literacy, and develop requisite job skills. This entry provides an overview of academic programs in correctional institutions, including information about inmate need and participation, a description of program types, an overview of program content and delivery approaches, and discussion of funding and public support.

Need and Participation

The need for academic programming is especially great among juvenile and adult inmates because they tend to be less educated and have lower literacy levels than their counterparts in the general population. For example, the rate of prior participation in special education programs among youth incarcerated in juvenile correctional facilities is 3–5 times the rate of all students in public schools, and approximately two thirds of state prison inmates have not completed high school.

Academic program availability varies substantially across states, as do requirements and incentives related to participation. According to data from the early 2010s, slightly fewer than half of states and the federal government have legislation or policy requiring mandatory education for inmates. Typically, participation in programs is required for those who have not achieved a specified level of achievement, such as a high school diploma, an equivalency certificate, or a minimum score on an academic assessment. Some states also offer incentives, such as the potential for early release, in return for participation in academic programs. Because juvenile offenders have a legal right to a public education, all facilities that serve incarcerated youth include correctional education programming.

Available data suggest that roughly one half of inmates participate in correctional education programs and that most participate in basic, secondary, and vocational programs. Participation in postsecondary programming is reported to be closer to 5 or 10% of inmates and tends to involve a small proportion of those who are eligible. Many inmates—even those with high school credentials—require substantial remediation to succeed in postsecondary courses because of poor academic preparation.

Participation in correctional education is frequently limited by available funding and capacity to deliver programming.

Program Content and Delivery

Information about the nature and extent of correctional education programming in the United States, such as the prevalence of different programs and how programs are delivered, is limited because states and correctional facilities rarely collect such data systematically and available data are often not comparable across sites. Information about correctional education in jails, for juveniles, and for individuals under community supervision is particularly scarce. This description, therefore, focuses on academic programs offered to adults in state and federal prisons, which house the majority of sentenced inmates in the United States. A primary distinction among correctional education programs is between those that are vocational (focused primarily on developing skills relevant to a particular job or workplace) and those that are academic (focused primarily on developing skills that lead to academic proficiency).

Available data suggest that nearly all juvenile and adult correctional facilities offer some form of education programming and that among academic programs, basic education (focusing on basic skills in mathematics, reading, writing, and English as a second language) and secondary education (focusing on instruction to prepare for a high school diploma or certificate of equivalency) are most prevalent. Other less prevalent forms of academic programs include special education programs (designed for individuals with learning challenges) and postsecondary programs (instruction that results in credit toward a college degree).

Basic education programs focus on language, reading, and mathematics skills for individuals who perform below the ninth-grade level. These programs are designed to develop basic academic knowledge and skills that will facilitate success in subsequent academic programs and the workplace. *Secondary education* programs focus on skills needed to obtain a high school diploma or equivalency certificate. Instruction frequently focuses on instruction in language arts, mathematical reasoning, science, and social studies knowledge and skills that are measured on assessments

required to obtain a certificate of high school equivalency. *Special education* programs tend to provide instruction for individuals under the age of 22 years with mental health, cognitive, or other learning impairments and are typically guided by education plans tailored to meet individualized student needs. These programs often combine academic topics such as literacy with employability and life skills. *Postsecondary* academic programs tend to include general education and liberal arts curricula that lead to an associate's degree. Degrees in science, applied science, general studies, and business are also sometimes offered. Typical courses include English, literature, writing, history, social sciences, and natural and physical sciences.

Programs are typically delivered via direct instruction by on-site instructors who may be facility staff members; faculty of a local college, university, or other partner organization; and/or volunteers from the community. Independent and small group work is also a component of many programs, particularly special education and postsecondary education programs, which tend to feature personalized and competency-based instructional approaches. Some academic programs also include peer education and tutoring, which involve inmates as both teachers and learners.

Various technologies are used as part of programming. These include computer-assisted instruction and assessment delivered via personal computer or tablet; interactive television (which allows for delivery of live lessons and use of interactive media to facilitate communication among students and an instructor in real time); and prerecorded audio and video lessons delivered via closed-circuit or satellite television, DVD players, and electronic files played back via computer or tablet. Security concerns prevent Internet use in most facilities; however, some models for limited Internet access and use of a simulated Internet environment have been used. Local computer networks are sometimes used to share instructional and other materials. Distance learning models are often offered by external organizations and include communication via U.S. mail and through a site coordinator who manages phone and e-mail contact with outside faculty. Community-based programs outside correctional facilities are also sometimes offered for those serving all or part of their criminal sentence under community supervision.

Oversight of academic programs varies across states. In some states, a single agency oversees education and other aspects of corrections. In other states, educational programs are overseen by a separate agency. At correctional facilities, administration and delivery of academic programming is usually managed through a combination of facility employees and contract personnel. For example, postsecondary academic programs are often implemented in partnership with one or more local community colleges. Course instructors come to the prison to teach courses, and institutional staff assist with courses by coordinating classroom space, providing security, and facilitating contact between students and instructors. For distance education programs, facility staff serve as liaisons with course instructors by distributing course materials, returning completed assignments, and proctoring exams.

The unique context of correctional facilities and needs of inmates suggest several considerations for program design and delivery, including the need to adapt curricula and instructional materials to address cultural and safety factors in these secure environments. Research on correctional education programs has identified several principles of effective programs, including:

- institutional commitment and support to ensure continuity of programming and availability of needed resources;
- maintenance of settings where students feel safe and supported in their work and where students have opportunities to learn together;
- implementation of programs by staff with appropriate knowledge, skills, and/or credentials who commit to their role in implementing programs and procedures and have accountability for outcomes;
- assessment and screening of students prior to participation and ongoing assessment to monitor their progress; and
- recognition of student achievement using interim milestones such as certificates.

Funding and Public Support

Various state and federal funding sources support correctional education programs. Personal and family funds and funding from private sources such as foundations are also used to

support programming. Changing attitudes about the value of correctional education among federal and state policymakers, prison administrators and staff, and the public have affected the nature and extent of support for and the availability of programs over time. For example, with the passage of the Higher Education Act in 1965, federal funds were used to support postsecondary correctional education leading to expansion of these programs through the 1970s and 1980s. In the mid-1990s, however, federal legislation eliminated these funds, which resulted in substantial reduction in available programming. In 2015, a pilot program was announced to restore some federal funding to support inmate participation in postsecondary programs through a selected group of postsecondary education institutions.

The success of correctional education programs and support for continued academic programming ultimately depends on the outcomes obtained. Research on prison educational programs has linked participation with a range of outcomes. These outcomes include development of academic knowledge and skills, improved behavior while incarcerated, reduced rates of recidivism, postrelease employment and education, and other public cost savings. Because the quality of available research on the impact of correctional education programs varies and there are few rigorous studies of impact, additional research is needed to explore questions about short- and long-term program effects, the models of instruction and curricula that are most effective in particular environments and with particular populations, and understanding of the costs and benefits associated with different types of programming.

ACADEMIC TRAINING FOR CRIMINAL JUSTICE CAREERS

Since the 1990s, opportunities for a wide variety of careers in the criminal justice arena have been increasing, as have salaries and benefits attached to these careers. Criminal justice is, by definition, multidisciplinary in nature and includes a wide variety of specialties. Formal academic training can be extremely valuable in securing and advancing in this employment. This will include employment on the local, state, and federal levels. This entry considers a wide variety of specialty areas and explains the academic training most closely related. Broad categories are broken down into subspecialties, and each section describes potential career paths and discusses the important academic foundations.

Academic Training on the Undergraduate Level

Many students entering academia at the undergraduate level may have a general interest in

criminal justice but be unsure of an exact career path. Therefore, they may wish to explore a number of possibilities.

Legal Studies and Criminal Justice

These broad and general majors can provide a foundation for any number of criminal justice pursuits working with the courts, the police, in a correctional environment (including probation and parole), and in the realm of national security. General criminal justice majors are offered at both the associate and the baccalaureate levels. Work ordinarily begins with a large survey course that includes an overview of the criminal justice system, some fundamentals of criminal law, the psychology of offenders and victims, and an introduction to a variety of career paths. Coursework that follows tends to be interdisciplinary in nature, examining systems from various perspectives, such as working with offenders, providing victim services, providing various treatments in a correctional setting, crime prevention, the fundamentals of forensic science, law and legal research, and ethics as applied from a variety of viewpoints. Curricula also put emphasis on electronic crime and the need for technical skills in the computer area. Information provided should assist students in determining if there is some area in which they wish to specialize.

General education courses are also a key element of this study. Associate degrees typically require over half of total credit hours to be in general education. Students are expected to gain skills in critical thinking, oral and written communication, psychology, and establishing interpersonal relationships. Choices can be made from history, political science, sociology, English, and any of the humanities. Students more interested in the forensic science area may select more courses from the hard sciences and mathematics.

Training for Law Enforcement

Law enforcement officers operate at the local, state, and federal levels. They investigate crimes, arrest offenders, patrol the streets and highways, maintain order in tense situations, mediate difficult issues, and collect and process information to be used in courts of law. Since the early 1990s,

philosophy as to where training should best occur has changed. Whereas police organizations were once very paramilitary in nature, emphasizing that training is best done within the organization, the preference has shifted toward recruiting officers with broader educational backgrounds. Over 80% of police officers are employed on the local level. However, states also employ police in specialized agencies. A number of federal investigative agencies also have career paths to offer, including the Federal Bureau of Investigation, Drug Enforcement Administration, Immigration and Customs Enforcement, Alcohol Tobacco and Firearms, U.S. Marshalls, U.S. Postal Inspectors, Internal Revenue Investigators, Park Police, and the U.S. Secret Service.

General education in the liberal arts is important for any police officer. The work requires a rudimentary knowledge of the law, understanding of cultural diversity, and the ability to build relationships with constituents, particularly for positions in community policing. A major in criminal justice can provide a solid foundation. However, more career-specific training is included in courses on police science geared toward the investigation and prevention of crime. Particularly in areas dealing with immigrant populations, acquisition of foreign languages can be invaluable.

Training for Careers in Corrections

Correctional environments include state and federal prisons, local jails, and probation and parole departments. Personnel are often called upon to provide specialty programs in areas such as substance abuse treatment, sex offender treatment, and anger management. Those with specialized training in general education, medical services, and facilities management (e.g., plumbers, electricians) are also in demand. From clerks to correctional officers to wardens to directors of agencies, knowledge of management and funding of prison operations can be very important, as is an understanding of prison culture from a sociological point of view. In correctional facilities, it is not unusual for promotion to occur from within. For example, in the U.S. Bureau of Prisons, it is common for wardens to have begun their careers as correctional officers; promotion is tied not only to performance on the job but also to knowledge

and skills the individual brings to the next level. A degree or additional academic education can provide a competitive edge.

Training in Forensic Science

Forensic science is the application of material from the hard sciences to the investigation of crime. Employment is available in independent forensic laboratories as well as in those established within larger police agencies. Specialists in this area also work as assistants to medical examiners. Since the turn of the 21st century, professionals in this area have become increasingly specialized. Subspecialties include arson, drugs, general crime scene investigation, serology, fingerprints, polygraphs, document authentication, and ballistics.

Education in basic science and the scientific method generally precedes forensic training. This may be in the form of a major in one of the physical or life sciences. An emphasis on computer science and technology can often be important as well.

Legal Training

An individual need not be an attorney to practice in the legal arena. Paralegals are often trained in 2-year academic programs. Skills are required in drafting basic legal documents, interviewing offenders and victims, researching areas of law relative to specific cases, and generally gathering information needed by attorneys. There are career paths for clerks, court administrators, and victim service providers. In the 21st century, foreign language skills are also at a premium.

Training for National Security

Since September 11, 2001, detection and prevention of terrorism has become a prominent concern. The Department of Homeland Security was established in 2002 and has a particular need for persons with expertise in cybersecurity, digital forensics, and network/systems engineering. To fill these very technical positions, the Department established the Cybersecurity Internship Program that recruits candidates from select graduate and undergraduate programs. Candidates who have

training in forensic analysis and the analysis of malicious code are particularly competitive. Student volunteers are also accepted for certain programs.

Academic Training on the Graduate Level

Students interested in pursuing graduate training in the criminal justice field may choose to enter law school and become attorneys. They may also select from a number of master's-level or doctoral-level programs in criminal justice or related disciplines.

Law School

In the criminal justice field, agencies at all levels (e.g., federal, state, and local correctional facilities, police departments, states' attorney general offices, district attorney departments) employ legal counsel. Attorneys are in demand to represent criminal defendants either privately or as agents of public defender services. They also serve as consultants to a variety of organizations involved with the criminal justice system (e.g., the National Alliance on Mental Illness).

Students considering law school typically major in some area of the liberal arts. Although a few institutions have a formal prelaw major, most counsel students in this direction simply through the advisement process. Law school typically takes at least 3 years of full-time training. Many programs include clinics in which students receive practical experience under supervision. Then, they are required to pass the bar exam in their respective jurisdictions before beginning practice.

Master's-Level Programs

For those wishing to pursue a career in teaching and/or research, there are numerous programs offering master's degrees in various areas of criminal justice and criminology. Master of Forensic Science degrees are also available for those seeking promotion and advanced positions in forensic laboratories. Smaller colleges and universities may have instructor positions open at the master's level. However, for the serious scholar seeking an academic position with a tenure track, a doctorate is typically required.

A number of institutions offer a master's degree in forensic psychology. These are generally 2-year programs that prepare the student to work in research positions in legal firms, work in correctional facilities and community mental health agencies providing counseling to offenders and victims, provide prerelease consultation, and assist in establishing suicide prevention programs, violence prevention programs, and various specialty treatment programs. These offerings often have research and clinical track options. Those on the research track receive fundamental training in research methodology, often for the purpose of preparing to go on for the doctoral degree. Those on the clinical track are likely to enroll in clinical internships at a facility. Graduates are prepared to do mental health screenings, make referrals for treatment, do case research, and recommend diversion programs. Those with master's degrees often work in collaboration with, and/or under, the supervision of a licensed psychologist.

Doctoral Programs

Many universities and professional schools offer doctoral degrees (either doctor of philosophy or doctor of psychology) in clinical or counseling psychology. In most jurisdictions, this is the minimum level of education required for a license to practice independently as a psychologist. In many jurisdictions, this is also the minimum requirement for testifying as an expert witness in criminal court. Completion of the degree typically takes 5–6 years and includes a year of internship and the completion of a dissertation. A number of programs offer various tracks from which to choose, including an emphasis or concentration in forensic psychology. The specific forensic emphasis generally comes after a solid clinical foundation is established. Clinical and counseling psychology programs typically include a variety of supervised practicum experiences either in a university-based clinic or at an outside agency.

Persons with a doctoral degree who have become licensed often work as supervisors of clinical work or chiefs of service in correctional facilities. For those working in forensic hospitals, the doctorate is generally required to obtain hospital staff privileges. Licensed psychologists are also eligible to engage in private

practice, work in court clinics, or provide consultation to the legal system. Those with advanced degrees are most likely to be chosen to engage in the formulation of policy and program evaluation. Academic positions are also available for those more intensely interested in research and teaching.

The predoctoral internship required for a doctoral degree in clinical or counseling psychology provides another opportunity to obtain training uniquely suited to the legal arena. This is composed of 2,000 hr of clinical experience, usually in the last year of graduate school. Internships are available with an intense concentration in forensic work or general correctional psychology (such as those offered by the United States Bureau of Prisons). Other programs offer major or minor rotations concentrated on forensic applications.

A few academic institutions offer a joint degree program. Here, students achieve a doctorate in psychology along with a law degree. This effort can take at least 10 years beyond a bachelor's degree. This is most often chosen by those destined for an academic career.

Postdoctoral Fellowships

Formal postdoctoral training in specialized areas of psychology developed during the 1970s. Typically, postdoctoral fellowships are 1 year, 2 years, or 1 year with the option of a second year. The great majority of these fellowships offer intensive clinical training and experience. They also provide extensive opportunities to network with other professionals in a particular specialty. Many states still require a year of postdoctoral supervision before being eligible for a license to practice independently; the postdoctoral fellowship fulfills this requirement. Some postdoctoral experiences are more formal than others. Some are accredited by the American Psychological Association and some are not.

It is common, and almost expected, for physicians to pursue board certification in their chosen specialty. For psychologists, this is much less common. However, postdoctoral training can prepare an individual to take the examinations necessary to become board certified. This leads to the highest level of specialty certification, the diplomate. This credential can be especially

valuable for those wishing to serve as expert witnesses. For those interested in academic research, fewer postdoctoral opportunities are available, and the credential is less emphasized by academic institutions.

ADAM WALSH CHILD PROTECTION AND SAFETY ACT OF 2006

On July 27, 2006, President George Walker Bush signed into law H.R. 4472, the Adam Walsh Child Protection and Safety Act of 2006 (AWCPSA 2006). The act addresses four issues:

- *P. L. 109-248* provides the reformulation of federal standards regarding sex offender registries for states, territories, and tribal lands, resulting in more inclusive, informative, publicly available, and uniform information about the protections for children from violent crime with an emphasis on the prevention of sex offenders' access to children.
- *P. L. 109-248* provides for the creation, amendment, or revision of grant programs designed to reinforce local, private, state, territorial, and tribal prevention law enforcement (particularly justice systems) to create, pool, and share resources to identify individuals who pose a threat of harm to children.
- *P. L. 109-248* strengthens a diverse set of amendments to federal criminal law and procedures that created processes for the civil commitment of convicted sex offenders upon their release from prison and provides for random search authority over sex offenders on probation or supervised release as well as new mandatory minimum prison sentences for new and existing federal sex offenses.
- *P. L. 109-248* promotes and prescribes a variety of administrative or regulatory initiatives and programs (e.g., funds for online child safety and fingerprinting programs) aimed at preventing crimes against children such as the National Child Abuse Registry.

The AWCPSA 2006 also gave state social service agencies with child protection responsibilities access to the National Crime Information Center (NCIC) database. The NCIC database provides social service agencies with criminal history records, domestic violence records, identification records, protection order records, and stalking records.

The AWCPSA 2006 provided procedures for states to conduct criminal background investigations on individuals and couples applying as prospective foster or adoptive parents to include the requirement for fingerprinting and records checks through the NCIC and National Child Abuse Registry before approval and placement. If a prospective foster parent or adoptive parent has a conviction for a felony involving child abuse or neglect, spousal abuse, crimes against children including child pornography, crimes of violence including domestic violence, rape, sexual assault, assault, battery, or homicide, his or her application would be disallowed.

The AWCPSA 2006 also eliminated states' *opt-out provisions* of compliance with the full provisions contained within the AWCPSA 2006 effective October 1, 2008. Section 209 of the AWCPSA

2006 also denoted a change to section 2258 of title 18, U.S. Code, increasing the penalties for a *covered professional* found guilty of failure to report child abuse to include a fine and incarceration for not more than 1 year. The term *covered professionals* applies to those individuals engaged in professional activities on federal land or in a federally operated or federally contracted facility.

The AWCPSA 2006 also requires the Secretary of the U.S. Department of Health and Human Services to create and maintain an electronic National Registry of Substantiated Cases of Child Abuse and Neglect accessible via the Department of Health and Human Services' Child Welfare Information Gateway.

After reviewing the circumstances that led to the AWCPSA 2006, this entry focuses on the implications of the act with regard to child protection.

Background

The Adam John Walsh Case

On July 27, 1981, at 12 p.m., 6-year-old Adam John Walsh was abducted outside of the Hollywood Mall in Hollywood, FL. A Sears and Roebuck department store manager alerted a security guard that several boys had become involved in a scuffle at a video game display. The responding security officer spoke with the boys who reported to be at the mall without their parents. Adam was part of the group but failed to inform the security guard that his mother was in the Sears lamp department. All the boys were escorted outside the mall and left alone without adult supervision; this was the last time Adam was seen alive.

On August 10, 1981, Adam's severed head was discovered 130 miles away in a Vero Beach Canal by two fishermen. The coroner determined that Adam died of asphyxiation before being decapitated. As of 2018, Adam's body was still unrecovered.

On October 21, 1983, Ottis Elwood Toole, a convicted serial murderer and serial arsonist, confessed to having murdered Adam. Toole later recanted his confession. According to Toole's niece, before his death on September 15, 1996, Toole again confessed to her that he had, in fact, killed Adam. Toole's niece notified police and Adam's family of Toole's deathbed confession. On

December 16, 2008, Hollywood Police Chief Chad Wagner officially announced Toole as Adam's killer and closed the case.

Awareness Born Out of Tragedy

Following Adam's disappearance, his parents, Revé and John Edward Walsh, Jr., discovered that there were no coordinated local, state, or federal resources available to assist in the search for missing children. Law enforcement could enter information on stolen vehicles, guns, horses, household items, and jewelry into the Federal Bureau of Investigation's (FBI) NCIC database but not missing or abducted children. As a result, they founded the Adam Walsh Outreach Center for Missing Children, a nonprofit organization, to serve as the first national resource for families with missing children and to lobby for legislative reform. Because of Adam's parents' efforts, Congress ordered the Federal Bureau of Investigation to begin entering information on missing children into its NCIC database.

Because of Adam's case and multiple others, on May 25, 1983, President Ronald Reagan declared May 25 to be National Missing Children's Day. On April 9, 1984, the Walshes cofounded the National Center for Missing & Exploited Children (NCMEC). On June 13, 1984, Reagan officially opened the center with a national 24-hr toll-free hotline for reports of information regarding missing children: 1-800-THE-LOST (1-800-843-5678). In 1990, the Adam Walsh Outreach Center for Missing Children was merged with the NCMEC.

Implications for Child Protection

With the passage of the AWCPSA 2006 came the creation of the Office of Sex Offender Sentencing, Monitoring, Apprehending, Registering, and Tracking (SMART). SMART administers standards for the sex offender registration and notification program outlined in Title I of the AWCPSA 2006. SMART also administers grants involving sex offender registration and notification under the AWCPSA 2006 and other programs as directed by the Attorney General. SMART works with and supports all U.S. states, territories, tribal governments, and public and private bodies involved

with sex offender registration and notification. It also acts as a supply line to these entities to ensure the protection of children and other members of the community.

Over the years, SMART has developed a website furthering access to its databases to those working with sex offender registration and notification. SMART provides resource materials to further the cause of child and community protection. Resources include educational and legislative materials. Government agencies, private for-profit, private nonprofit, faith-based organizations, students, and the public all can subscribe to and receive email updates from SMART at NewsFromSMART@ncjrs.gov.

Because of the creation of the NCMEC and passage of AWCPA in 2006, more than 211,000 missing children have been recovered as of 2016. The NCMEC currently has six operating divisions: Missing Children, Exploited Children, Case Analysis, Family Advocacy, Training, and External Affairs. According to the NCMEC's 2014 Annual Report, its CyberTipline (www.cybertipline.org) received more than 3.3 million reports, and its call center received more than 4 million calls since inception in 1984. NCMEC reports the review of more than 132 million child pornography images using its Child Victim Identification Program. NCMEC assisted local, state, federal, and tribal law enforcement agencies in identifying more than 2,480 victims bringing the total number of child pornography victims identified to 7,917. NCMEC indicated that in 2014 alone the CyberTipline experienced an increase of more than 600,000 reports of child pornography, representing 98% of the reports received.

The NCMEC also instituted its Notice Tracking System. Notice Tracking System is a voluntary initiative with the Internet industry, whereby the NCMEC notifies companies when their corporate servers are discovered to contain or have downloaded or saved web pages depicting apparent child pornography. In 2014, the NCMEC provided over 21,000 notices to companies of apparent child pornography located on their corporate systems. As a direct result, the affected companies were able to respond rapidly and have these images investigated and removed from their corporate servers in fewer than 28 hr of initial notification.

The NCMEC's Child Sex Trafficking Team in conjunction with the Federal Bureau of

Investigation and the Child Exploitation and Obscenity Section of the U.S. Department of Justice provides support to the Innocence Lost National Initiative. Since its partnership in 2003, the Innocence Lost National Initiative has developed more than 70 dedicated task forces in cooperation with local, state, and federal law enforcement agencies and the U.S. Attorneys' Offices. More than 4,800 children have been rescued with the prosecution of more than 2,000 offenders, and the seizure of real property, vehicles, and monetary assets of more than \$3.1 million because of these task-force partnerships. In at least 15 cases, the offenders received sentences of incarceration for life.

In October 2015, the Innocence Lost National Initiative conducted Operation Cross Country, resulting in the recovery of 149 sexually exploited children and the arrests of more than 150 offenders. More than 500 law enforcement officers and 100 victim specialists nationwide took part in the operation. In the sex trafficking component of Operation Cross Country, 168 trafficking victims were recovered and 261 offenders were arrested.

The death of 6-year-old Adam John Walsh resulted in a legacy that has and continues to save the lives of numerous children.

ADVERSARIAL ALLEGIANCE

Courts often rely on expert witnesses to better understand complex scientific or clinical issues that may be unfamiliar to judges, attorneys, or

layperson jurors. Sometimes, courts appoint these experts directly, but more often, the adversarial parties select and retain the experts. In criminal trials, the prosecution or defense might select an expert to answer a question about scientific evidence, including mental health evidence on issues such as trial competence, sanity at the time of the offense, or risk of future violence. The opportunity for opposing sides to select experts raises obvious questions: Can experts who are retained by one side in adversarial legal proceedings offer the court genuinely objective findings and expert opinions? Or are these experts inevitably biased by the adversarial arrangements in which they work? Consistent with these concerns, recent research reveals strong evidence of *adversarial allegiance*, the tendency for some experts to drift from strictly objective findings toward findings that better support the party that retained them.

Legal scholars and other observers have long speculated that expert witnesses are probably biased toward the party that pays their fees. However, despite these long-standing concerns about allegiance and warnings against this type of bias, there has historically been no rigorous research on the topic. This entry reviews recent evidence of allegiance among forensic experts, explores potential explanations for allegiance effects, and discusses the wide range of forensic settings across which evidence allegiance effects have been observed.

Forensic Assessment Instruments Allow Studies of Allegiance

One of the reasons there has been little systematic proof of adversarial allegiance is that isolating and quantifying the effect of allegiance across cases is quite difficult. Experts may answer different types of questions in different cases, use different methodologies in similar cases, and express their opinions in different terms, making it hard to compare the results across many cases. One important development from forensic psychology, however, has made it easier to study certain types of expert opinions. Specifically, forensic psychologists increasingly use forensic assessment instruments to measure constructs such as psychopathic personality, risk of violence, or risk of sexual reoffense. These instruments have become increasingly popular; thus, it is common for evaluators to use

the same instrument across many similar cases, and for opposing evaluators to use the same instrument to assess the same offender. Many of these forensic assessment instruments are well designed and well researched, with ample evidence that the instruments can be highly reliable. In other words, different clinicians using the same instrument to score the same offender usually assign very similar scores, with no evidence of one type of rater assigning higher scores than another. However, if scores assigned in adversarial contexts reveal poorer agreement in the field and the direction of disagreement appears systematically related to the forensic expert's side of retention, such a pattern would suggest that the poorer agreement is somehow attributable to adversarial arrangements.

Field Research Suggests Allegiance

Since 2008, studies have used exactly this strategy of examining instrument scores to explore the possibility of allegiance among forensic mental health experts. In particular, researchers have examined scores on the Hare Psychopathy Checklist-Revised (PCL-R), a widely used instrument designed to assess psychopathic personality features that has become common and influential in forensic assessments of risk of violence or sexual violence, and the Static-99R, the most widely used instrument to quantify the risk of sexual reoffending.

In the first of these instrument-focused field studies, researchers collected PCL-R scores assigned by prosecution-retained and defense-retained psychologists in trials addressing sexual offenders. In the majority of these cases, there was a significant difference between the two PCL-R scores, and in these instances, it was the prosecution-retained evaluator who had assigned a higher score. In other words, prosecution-retained experts assigned higher risk scores to offenders (consistent with the prosecution's perspective of the case), and defense-retained experts assigned lower risk scores to the same offenders (consistent with the defense perspective). Similarly, researchers found continued evidence of bias in the scores experts assigned on instruments designed to predict future sexual offending.

Similar patterns of score discrepancies that suggest adversarial allegiance have emerged in case

law reviews of U.S. and Canadian criminal cases. Evidence of allegiance effects has also emerged in surveys of score reporting and interpretation practices. Evaluators who tend to work for the prosecution favor reporting practices that suggest higher risk and less measurement error, while those who work for the defense favor reporting practices that suggest lower risk and more measurement error.

Thus, a growing body of recent research suggests that the scores clinicians assign and the way in which they interpret those scores are, at least to some extent, related to the side for which they are working.

Allegiance Effects and Selection Effects

Field studies strongly suggest adversarial allegiance, but there are other possible reasons that opposing experts may reach different opinions. One possibility involves selection effects. Because experts are not randomly assigned to sides, the field study findings demonstrating differences in expert opinions may be a product of how attorneys select experts for their cases (selection effects), as opposed to the experts' decision-making after they begin to work on the cases (allegiance effects). Indeed, research demonstrates substantial individual differences among experts in their tendencies to reach particular forensic opinions, a pattern of variability that may be exploited by savvy attorneys. A savvy defense attorney, for example, would almost certainly select an expert with a greater history of reaching opinions that support insanity, incompetence, or low violence risk. A savvy prosecuting attorney would almost certainly select an expert with a greater history of reaching opinions that support sanity, competence, or high violence risk.

Experimental Research Demonstrates Adversarial Allegiance

Traditionally, observational field studies are the first step in scientific research, allowing researchers to observe phenomena and generate hypotheses. To conclusively demonstrate a phenomenon or to identify its cause, however, researchers must conduct strict experiments in which they carefully control the many factors that could influence or explain the phenomenon observed. To demonstrate the

phenomenon of adversarial allegiance—as distinct from other forms of bias or selection effects—requires a situation in which attorneys are randomly assigned forensic experts, experts are randomly assigned to attorneys, experts have access to exactly the same materials, and researchers have access to data from all experts who conducted an evaluation. Only in such a scenario, discrepant scores from opposing evaluators would be clearly attributable to adversarial allegiance rather than attorney selection effects, expert selection effects, or genuine differences in the data available to opposing parties.

In the only experimental study of this sort, researchers recruited over 100 practicing, doctoral-level forensic psychologists and psychiatrists and deceived them to believe they were performing a formal, large-scale forensic consultation. Unbeknownst to them, these forensic experts were randomly assigned to either a prosecution-allegiance or defense-allegiance group in which they were paid by what they believed was either a *public defender service* or a *special prosecution unit*. These participants met with an attorney who posed as leading either the public defender service or the specialized prosecution unit and requested that they score particular risk instruments on the basis of extensive offender records (a type of consultation that is common in forensic practice). Participants were led to believe that, as a group, they were reviewing and scoring cases from a large cohort. In truth, each participant was scoring the same four case files of authentic case materials.

Overall, the risk measure scores assigned by prosecution and defense experts showed a clear pattern of adversarial allegiance. That is, experts who believed they were working for the prosecution tended to assign somewhat higher scores and experts who believed they were working for the defense tended to assign somewhat lower risk scores. Allegiance effects were stronger for the PCL-R, a measure that requires more subjective clinical judgment, than for the Static-99R, a more structured measure that permits less judgment.

Of course, not every expert demonstrated biased scoring, but when researchers compared all possible pairings of opposing defense and prosecution experts, many demonstrated large score differences in the direction of adversarial

allegiance. This pattern could not be explained by chance or by other factors such as evaluator experience. Overall, findings from this rigorous experiment provided strong evidence that even scores on ostensibly objective forensic instruments can be compromised by adversarial allegiance, at least among some experts.

Potential Explanations for Adversarial Allegiance

Findings from field studies, surveys, and the experiment described earlier converge to show that performing an evaluation for one side in an adversarial setting can influence an expert's decisions. This adversarial allegiance effect is distinct from, but can be compounded by, selection effects, evaluator differences, and other possible causes of differences between opposing evaluators.

In any adversarial case, there is a pool of possible evaluators that an attorney may retain. These evaluators differ to some extent in their attitudes, their thresholds for coming to certain conclusions, and the typical scores they assign on forensic assessment instruments. Attorneys who are familiar with these differences can take advantage of them by selecting an expert who appears more favorable toward their side of the case.

After an attorney retains an expert, however, the expert's opinion (at least in some cases) begins to favor the retaining party to a greater extent than the case data warrant. None of the allegiance studies have empirically identified the precise mechanisms that cause these allegiance effects, but there seem to be three broad and overlapping theories. The first broad theory is relational: Adversarial allegiance results from social and psychological processes that encourage evaluators to feel as if they are on a side or team. The second broad theory is that allegiance results from common decision-making errors and cognitive biases. This viewpoint also holds that adversarial allegiance is unintentional but attributes allegiance effects primarily to well-known, common cognitive errors in human judgment, such as confirmation bias. Although the relational and cognitive-error explanations for adversarial allegiance effects are conceptually distinct, they probably interact. The third broad theory differs from the first two by assuming that adversarial

allegiance results from more intentional processes and motives that can best be summarized as financial gain.

Each of these mechanisms could have contributed to the allegiance effects among evaluators in field and experimental studies, but of course, different clinicians are probably influenced to different degrees by different mechanisms.

Adversarial Allegiance Is Not Unique to Mental Health Experts

Although adversarial allegiance has been best studied in *soft sciences* such as psychology, there is no reason to believe that only experts in mental health disciplines feel a pull toward allegiance. Observers have documented anecdotal evidence of adversarial allegiance in a variety of fields, ranging from forensic medicine to accounting. Scrutiny of the forensic sciences underscores the breadth of biases similar to adversarial allegiance. In 2005, the U.S. Congress mandated the National Research Council (NRC) to review the state of forensic science. The NRC critically assessed a wide range of forensic science disciplines, such as analyses of DNA, hair, fibers, tool marks, bite marks, and ballistics. In a 2009 report, the NRC concluded that forensic scientists are prone to a variety of contextual biases, including some that emerge because they lack independence from those requesting their services. For example, forensic science labs tend to work closely with law enforcement officials and prosecutors. Thus, they may operate much as members of those teams, receiving information about suspects and case developments that is irrelevant to the analyses they perform. In other words, operating as a member of a side or team (a form of allegiance effect) may lead to errors in interpretation and decision-making.

Consistent with the NRC's concerns, emerging research has clearly documented subjectivity and bias even in the forensic science procedures that courts have considered most reliable, such as analyses of DNA and fingerprints. This research revealing biases in forensic science procedures has proceeded in parallel with similar research addressing adversarial allegiance in forensic mental health evaluations. Although both research programs have revealed compelling evidence of bias, neither has yet developed to a point that specifically

identifies, at least via controlled experiments, the precise mechanisms or processes underlying these biases.

All the forensic experts who work in adversarial contexts are asked to form opinions by parties that are motivated to achieve a certain outcome. Consequently, all forensic experts inevitably approach their task with certain assumptions, expectations, and even desires. These influences—which may be described as allegiance effects, expectancy effects, or context effects, depending on the details—may shape forensic experts' perceptions and interpretations of the data they are asked to consider.

ADVOCACY ORGANIZATIONS

Advocacy organizations are nongovernmental organizations (NGOs) concerned with civil and human rights. They respond to the needs of oppressed or marginalized individuals and groups and seek to redress actual or perceived social, political, or economic inequities. In their modern forms, they are sometimes incorporated as non-profit charitable organizations but may also be political action committees. Advocacy organizations can be secular or religiously affiliated, partisan, or nonpartisan. Their scope varies from local (e.g., the New York Society for the Prevention of Cruelty to Children) to global (e.g., Amnesty International). Their missions may be relatively specific (e.g., National Organization for the Reform of Marijuana Laws) or more general (e.g., American Civil Liberties Union). Advocacy organizations seek to influence public opinion, government policy, and/or law through education, research, and scholarship; involvement in the political process; or litigation. Related activities, in some cases the primary focus of the group, may include direct action, such as food distribution, provision of medical care, prison visitation, and so on. With the advent of the Internet, many such groups now function largely online and thus potentially reach a worldwide audience. This entry discusses the origin, nature, and function of advocacy organizations, notably those concerned with criminal justice issues.

History

From their earliest and local incarnations in 19th-century Europe, advocacy organizations have been concerned with improving the human condition. Those focusing on criminal justice matters, such as prison reform, have strong roots in religious tradition.

Origins

Advocacy organizations are often associated with reform initiatives. They evolved in Europe and North America during the Enlightenment (late 17th–early 19th centuries), a period of increasing religious toleration and humanitarianism, and one

of increasing interest in the role of science in improving the human condition. Prior to this time, poor relief and other forms of charity, such as there were, were essentially the province of the state and religious orders. These new groups were often a means by which interested members of the public could involve themselves collectively, despite differences in social class, and potentially to greater effect in worthy causes.

Among early British groups, the Philanthropic Society, founded in 1788, supported reform efforts on behalf of criminal children. The Jacobin Club, the Cercle Social, and the Society of Friends of the Rights of Man were French political activist groups organized during the Revolutionary era. These groups pressed grievances against the monarchy and rival groups and notably, in some instances (e.g., the Society of Revolutionary Republican Citizenesses), gave voice to particular women's rights agendas. In 1863, the International Committee of the Red Cross was formed in Switzerland and became one of the first advocacy organizations with a global reach. The first Geneva Convention was held in 1864 under its auspices.

In the United States, a variety of causes, including abolitionism (the Pennsylvania Society for Promoting the Abolition of Slavery, for the Relief of Free Negroes Unlawfully Held in Bondage, and for Improving the Condition of the African Race was formed in 1775), women's suffrage (National Woman Suffrage Association, 1869), and temperance/prohibition (Woman's Christian Temperance Union, 1874) began attracting popular support during the late 18th and 19th centuries. By the early 20th century, the National Association of the Deaf (founded 1880), the Indian Rights Association (founded 1882), and the National Association for the Advancement of Colored People (founded 1909) had been formed.

The Quaker Influence

Particularly prominent among early modern reform advocates were members of the Quaker sect, founded by George Fox (1624–1691), who also founded the prison reform movement. Over the past 300 years, and beginning in England, the Quakers have regularly been associated with a range of social causes, including prison and psychiatric asylum reform initiatives, abolition of

slavery, promotion of women's suffrage, and the concerns of aboriginal persons. At the same time, they were influential in the creation of the early modern penitentiary, particularly in the concept of isolating prisoners as a means of rehabilitating them (as distinguished from the reform of inhumane prison conditions per se). Among the earliest and most prominent Quaker reformers was Elizabeth Fry (1780–1845), an Englishwoman who was active in prison reform in the United Kingdom and Europe. Her efforts endure in the eponymous Elizabeth Fry Societies in the United Kingdom, Canada, Australia, and New Zealand. Today, the Quakers' continuing concern with prison issues may also be seen in organizations such as the Prisoner Visitation and Support program and the American Friends Service Committee.

The Evolution of Prison Reform Groups

Fox and his wife Margaret (1614–1702) were active in Great Britain, Europe, and the American colonies on behalf of the nascent prison reform movement. Their activities resulted in their own incarceration on several occasions. During his travels, Fox met and influenced William Penn (1644–1718), founder of the colony of Pennsylvania. Philadelphia subsequently became the center of Quaker activity in the colonies and then the United States. The career of the English sheriff John Howard (1726–1790) provided a further impetus. His books cataloging the prisons and jails he inspected in England brought wide attention to the often squalid living conditions inmates, including children, experienced in these facilities. As a result, and coincident with rising societal concern about human rights, increasing numbers of individuals, beginning in England, then throughout Western democracies, took an interest in various aspects of the criminal justice system.

Among the oldest continuously existing advocacy organizations in the United States is the Pennsylvania Prison Society (established in 1787 as the Philadelphia Society for Alleviating the Miseries of Public Prisons). Its founding members included Benjamin Rush (1745–1813), a signer of the Declaration of Independence and prominent American psychiatrist. When the Philadelphia Jail

opened in 1790, it was the first facility to promote isolating prisoners in order to promote reform, a principle that was integral to the first of the large penitentiaries (Auburn, Pittsburgh, and Philadelphia) built in the early 19th century. These and similar institutions failed to produce the desired results. At mid-century, inquiries found some of them to be compromised by corruption, overcrowding, and harsh discipline. Yet the reform movement endured. The first Geneva convention occurred in 1864, setting the stage for the establishment of international laws in later conventions that included the treatment of prisoners. The Howard League for Penal Reform was founded in England in 1866. In 1870, the National Congress on Penitentiary and Reformatory Discipline (later the American Correctional Association) was founded.

The American Civil Liberties Union was founded in 1920. Its broad mandate includes a range of criminal justice issues from capital punishment to prisoners' rights and mass incarceration. Over the years, it has participated in many court cases. In one notable instance, it supported Clarence Gideon in his petition (*Gideon v. Wainwright*) before the U.S. Supreme Court. The outcome of that case established the constitutional right of defendants to representation by counsel. Since that time, other NGOs, such as Amnesty International and Human Rights Watch, focusing on prisoner rights and welfare have proliferated in the United States and abroad.

Contemporary Advocacy Organizations and the Criminal Justice System

Advocacy organizations have evolved to respond to changing societal concerns, and many now function on a global scale, including some with a primary or secondary focus on criminal justice issues.

Conceptualizing Contemporary Advocacy Organizations

Advocacy organizations do not lend themselves to discrete categorization. For present purposes, the defining characteristics are that they are NGOs and that they support civil and/or human

rights. However, interests may be opposed to each other in framing these issues. Organizations advocating the legalization of one or more drugs (e.g., National Organization for the Reform of Marijuana Laws) act counter to the goals of groups like Citizens Against Legalizing Marijuana. Similarly, the National Rifle Association holds that broader ownership of firearms (excluding felons and persons with serious mental illness) promotes public safety and reduces crime, while the Brady Campaign to Prevent Gun Violence takes the opposite position.

Labor unions, religious groups, private foundations, and professional associations may serve advocacy functions ancillary to their core missions. For example, the Salvation Army provides food and shelter to the poor and homeless and conducts prison ministries but has also entered into a partnership with Indiana University to study and ameliorate poverty. Further, these organizations' activities may be interrelated. The Vera Institute of Justice has received funding in the form of grants from the Bill & Melinda Gates Foundation. Vera Institute of Justice, in turn, partners with local, state, and national governments and with other nonprofits. One such collaboration involved Vera Institute of Justice with the New Orleans Police and Justice Foundation, another nonprofit organization, to develop the New Orleans Pretrial Services.

It is also helpful to consider advocacy organizations in terms of the aspects of the criminal justice system they seek to impact. Following is a nonrepresentative sample from among hundreds of organizations with a focus on criminal justice issues:

- American Civil Liberties Union: Broad civil rights mission includes a range of criminal justice initiatives, often utilizing litigation to promote these.
- Amnesty International: global agenda, prevention and redress of human rights abuses including torture; advocates for political prisoners.
- Canadian Association of Elizabeth Fry Societies: advocates for and supports women and girls involved in the criminal justice system.
- Death Penalty Information Center: provides information, research, and analysis on range of death penalty issues.

- Just Detention Now International: prevention of sexual abuse in jails and prisons.
- The Fortune Society: supports successful community reentry from prison and alternatives to incarceration.
- The Innocence Project: exoneration of wrongly convicted persons.
- The Marshall Project: utilizes media to bring attention to criminal justice issues.
- National Association for the Advancement of Colored People Legal Defense and Educational Fund: racial justice agenda.
- National Organization for Victims Assistance: publicizing, promoting, and public education concerning crime victims' rights.
- Prison Activists Resource Center: seeks to abolish prisons.

Criminal Justice System–Advocacy Organization Partnerships

Consistent with the notions of reform, relationships between some advocacy organizations and the criminal justice system are regularly adversarial. However, there are instances in which advocacy NGOs and elements of the criminal justice system have found common ground. The New Orleans Pretrial Services, for example, was the outcome of one such partnership. The National Alliance on Mental Illness has collaborated with police forces in Memphis, TN, and several other cities to provide officers with crisis intervention training to improve outcomes of encounters with persons in the community dealing with acute mental illness. A task force convened by Correctional Service Canada and concerned with incarcerated women included representatives from the Canadian Association of Elizabeth Fry Societies and the Native Women's Association of Canada.

American Psychological Association (APA) and Criminal Justice Reform

The APA, the largest psychological association in the United States and a 501(c)(3) tax-exempt organization, has been involved in several criminal justice issues. For example, APA backed the Sensenbrenner-Scott Safe, Accountable, Fair, and Effective Justice Reinvestment (SAFE Justice) Act of 2015, H.R. 2944. This bill is intended to

support improved care for prisoners and reduce the numbers of persons housed in the federal prison system.

Notably, however, APA itself has also been the object of a high-profile criminal justice reform initiative. An agreement between APA and the Department of Defense authorizing psychologists' involvement in the interrogation of captured enemy combatants from the wars in Afghanistan and Iraq generated considerable controversy among the membership. Some of the methods used in these interrogations were widely considered to be torture. The Coalition for an Ethical APA led a grassroots protest against the policy permitting psychologists' participation. An independent investigation and related media coverage resulted, in 2015, in a change to organization policy entirely banning participation in these interrogations.

AGING AND OLDER INCARCERATED OFFENDERS

The increase in the aging prison population is a major concern for policymakers in nearly every region of the world. The rapid growth of older adults in prison is particularly problematic in the United States, which has the largest incarceration rate per capita. Baby boomers and punitive sentencing practices have left prison administrators in a challenging position to accommodate the special needs of the rapidly growing prison population. In keeping with the mandates of the Eighth Amendment to the U.S. Constitution, which prohibits inflicting cruel and unusual punishment, prisoners have a right to timely access to an appropriate level of care, including the right to a medical judgment for serious medical needs. Yet, it has been acknowledged that medical facilities in many state and federal prisons are simply unequipped to effectively provide the appropriate care to treat advanced chronic diseases commonly found among older inmates. With older inmates disproportionately accounting for an escalating prison health-care

expenditure, how to best manage a geriatric prison population has emerged as one of the most significant concerns for prison administrators nationwide. This entry discusses the critical policy and program issues faced by the correctional system in order to effectively respond to the special housing, health, and reentry needs of a rapidly growing and diverse aging prison population.

A Graying Prison Population

Designated by the United Nations as a special needs population, the majority of states classify older inmates as individuals 50 years and older. This classification is based on the process of accelerated aging, which is attributed in older offenders to high-risk personal histories, chronic health conditions, poor health practices, and alcohol and drug abuse, coupled with stressful conditions of prison confinement.

Regardless of the age chosen to define an older inmate (e.g., 50, 55, or 60), the number of geriatric inmates in many state and federal prisons has been rising steadily since the early 1990s. According to the U.S. Bureau of Justice Statistics, the number of inmates age 50 and older has increased from 33,499 in 1991 to more than 280,000 at the end of 2014. The older prison population currently makes up 18% of the total prison population, a dramatic increase from 5% in 1991. Based on projected growth patterns and current sentencing policies, this group of inmates is projected to reach 500,000 by 2025. According to the Human Rights Commission, by 2030, inmates age 55 and older will comprise one third of the total prison population. Contributing to this enormous growth is the significant increase in arrests for specific felony crimes such as murder, sexual crimes, robbery, larceny-theft, drugs, and aggravated assaults among those in the 50 and older age category. Overall arrests for older offenders have increased 73% from 534,021 in 2002 to well over 923,000 in 2012, which is illustrative of the current geriatric crime trends.

Diverse Aging Prisoners

Inmates differ based on characteristics such as age, race/ethnicity, marital and family relationships, gender, mental and physical health statuses, and criminal offending histories. Such diversity

has important implications for coping mechanisms adopted for adjustment purposes. Although the projected mean age for the older offender is 57 years, there are marked differences when it comes to health-care needs between inmates in their early 50s and those in their 90s. As documented by Ann Carson in 2015, the vast majority are men (94.5%), and they are disproportionately minority racial ethnic groups (Black = 32%, Latino = 16%, Other = 9%) compared to 43% Whites. Only about one third of older inmates are married, but the majority have children and grandchildren on the outside. Prisoners often enter prison with backgrounds of poverty, little advanced education, and underdeveloped coping skills. Histories of cumulative trauma are an important consideration among older people in prison, especially for older women.

Sentence history and length are often key determinants of stressors faced and subsequent coping mechanisms developed for adjusting to incarceration. Older inmates entering prison after the age of 50 years collectively comprise slightly less than half of the total geriatric prison population. They frequently suffer from prison shock and difficulties in coping with late-life imprisonment, experience estrangement from families due to violent crimes committed against family members, suffer grief issues related to social losses, and may express fear associated with late-life incarceration, especially for frail vulnerable inmates. Other inmates have reached later life while incarcerated. Typically, these older inmates face complex problems in the areas of preserving external relations, establishing and maintaining internal relationships, and coping with physiological deterioration. Many long-term inmates have outlived family members or have slowly disengaged from them, which may impact eventual release plans. There is a realization that dying in prison is a likely outcome, and the fears associated with this process are commonplace. Loss of ability to make personal decisions due to dementia or other mental health disorders, as well as the gradual decline in functional health conditions, restrict prison movement.

Special Health Concerns

Older inmates are usually in worse health than their counterparts outside prison because they

develop health issues much earlier due to their previous lifestyle, socioeconomic factors, and the prison environment. This rapid decline or accelerated biological aging has been attributed to high-risk behaviors (e.g., smoking, drugs, alcohol, unhealthy diets) prior to incarceration, coupled with the stressors of prison life.

In general, aging prisoners rate their health as fair to poor, having deteriorated since incarceration and with a high degree of comorbidity. On average, older inmate samples report three to four chronic conditions, including arthritis, hypertension, heart diseases, emphysema, diabetes, and intestinal problems as leading health issues. About half of all inmates report having health problems at the time of arrival to prison. In addition to possessing a variety of physical health symptoms, many convicted felons enter the criminal justice system with acute mental health issues. Large nationwide surveys have estimated that 15–30% of aging prisoners have chronic mental health concerns. In particular, older inmates suffer from anxiety disorders, emotional problems, alcohol/drug abuse, post-traumatic stress disorder, and many have high rates of depression and personality disorders. Dementia is becoming a greater concern among older offenders who report advanced memory and cognitive disorders. Suicide ideation is also common among those inmates with excessive pain and chronic health conditions.

Programs and Housing Facilities

There has been an ongoing debate for some time on the advantages and disadvantages of both mainstreaming and segregating older inmates. Currently, the overwhelming majority of aging inmates are housed in age-integrated facilities. With the rapid increase of the aging prison population, it is virtually impossible for states with large numbers of aging inmates to provide housing in secure geriatric facilities. However, given the fact that older inmates are a diverse group, those supporting an integrative approach feel that housing arrangements should be based on need rather than solely on age. Living in a specialized facility can lead to inactivity, lack of work opportunities or access to prison programming, and, in some cases, eventual withdrawal and increased

depressive states. Also, being assigned to a special facility may create geographical barriers for inmates to want to remain in close proximity to family and friends. However, one argument in favor of age segregation has centered on the safety of older inmates, as older, frail inmates are frequently threatened. Although fewer incidents of victimization are reported in women's institutions than in men's, some harassment, cussing, teasing, pushing around, and other minor incidents have been reported.

Over the past 25 years, a significant number of states have had no choice but to build special needs facilities to accommodate the increasing number of geriatric inmates. A little over half of the states now provide geriatric accommodations, ranging from selected clustering, dedicated units, freestanding prisons, or dedicated secure nursing home facilities. Special geriatric accommodations provide aging inmates with a quieter living environment and are considered safer than living in the general prison population. Handrails, lower bunks on main-floor tiers, elevated toilets, and wheelchair accessibility are provided in most specialized units. When prisons have low security risks, the facilities often permit the older offender increased privacy by designing rooms with doors. Additional amenities in newer facilities include prison-controlled thermostats, fluorescent lighting, strobe light fire alarms, and nonslip flooring services. In some prisons, inmates are provided hospital-style beds equipped with extra padding and toilets, sinks, and showers that are handicap accessible. In some, inmates use a therapeutic gym equipped with a pool table configured at a lower height to accommodate wheelchairs. Closed-captioned television and specially equipped phones are available for the hearing impaired.

Reentry Challenges

Making a successful transition back to the community for the aging prison population involves effective case management planning and public health partnerships. The case management process includes not only placement orientation but also eligibility for Medicaid, Medicare, disability, Social Security benefits, and available veterans' programs. Public health partnerships with specific nursing homes, public housing, home- and

community-based care, hospice/palliative care, occupational therapy skills, and public and mental health agencies can all be instrumental in development of a treatment plan that will serve to facilitate the reentry process. Locating volunteer companion services and enhancing family connections and other social supports are of equal importance. Reentry challenges remain, however, as some older offenders suffer from institutional dependency and have a difficult time transitioning back to a free society. Mental illness and crime histories are also barriers to renewing a life on the outside. Many have disengaged from or outlived family members. Finally, there may be a general lack of organized structures available for aging inmates, who have spent the better part of their adult lives incarcerated, to successfully succeed.

Despite these challenges, research has found that recidivism rates for older inmates are in the 3–5% range. As harsher prison policies have resulted in longer prison sentences and extensive and costly medical needs, some states are examining their sentencing practices. Although 15 states have provisions for age-related geriatric release, it is well-documented that these provisions are rarely implemented. Political pressure, public opinion, and narrow eligibility criteria procedures often discourage inmates from applying for release. Due to the complicated and lengthy referral and review processes, in a large number of cases, older inmates simply die in prison before a decision is reached to make a formal pardon or they are moved to a facility that can provide adequate health care. It has been recommended that states continue to examine early release for geriatric inmates as a cost-saving measure. There is little consistency or clarity concerning attitudes toward the well-being of those near the end stage of life.

Future Challenges

The aging prison population will no doubt continue to pose a significant dilemma for decades to come as officials responsible for executing prison policy grapple with the problems associated with this special subgroup of prisoners. With an economic crisis challenging budgets to simply maintain the status quo, prison officials

will be hard pressed to provide safe living conditions for the increasing number of frail, older prisoners. A variety of steps must be taken to ensure the safety and well-being of older inmates, including:

- an understanding of inmate diversity including race, gender, crime classification, education, and physical and mental health characteristics,
- the development of a comprehensive and gender-sensitive program for older adults that fosters personal growth and accountability and value-based actions that lead to successful reintegration into society,
- staffing needs and professional training for corrections officers and care providers working with older persons, including training in the mental and physical processes of aging, and the accompanying appropriate communication techniques,
- monitoring of older prisoners to ensure they are receiving suitable housing, medical care, and are not being victimized,
- sentencing alternatives for the mentally ill and the utilization of compassionate release when state policies permit,
- assessment of custody and security rules that impose unnecessary penal harm to older inmates,
- the care of dying inmates, particularly in prison systems that infrequently utilize compassionate release, and
- addressing the tension between custody and health-care delivery in determining the best practice options in which long-term care is provided.

The graying of American prisons is a complex issue and one that will remain at the forefront for decades to come. With the age 65 and older population doubling from its current 40 million to over 80 million by 2050, the prison system will continue to face multiple challenges as it finds ways to accommodate an increasing number of impaired and older inmates.

AGING AND OLDER INCARCERATED OFFENDERS, PALLIATIVE CARE OF

As the offender population ages, the need for palliative care behind bars increases. Palliative care is a specialized medical care intended to improve the quality of life of patients with life-threatening and serious illnesses through prevention and relief of symptoms, both physical and emotional. Models of palliative care that operate in the community must be adapted for use behind bars.

After the enactment of strict sentencing guidelines in the 1970s, even low-level drug dealers were given long prison terms. This resulted in a huge increase in the number of older inmates; individuals older than 50 years are the fastest growing population in prison. The older inmates have more expensive medical needs than younger people, and incarcerated individuals have more health problems than individuals in the community. Since most prisoners are from poorer families in poorer neighborhoods, often they have not led healthy lives or had access to quality health care. High rates of drug abuse and, especially for women, physical and sexual abuse take their toll on prisoners' health. Further, prison environments are not designed to optimize health or health care, leading to an accumulation of problems. As a result, inmates are estimated to be 5–10 years older than similar community dwellers, accentuating the needs for palliative care.

In the community, palliative care is fairly straightforward, if not always available. For those behind bars, however, barriers exist. Palliative care is first about symptom management. Older prisoners with serious illnesses, such as cancers, cardiac diseases, respiratory diseases, kidney failure, HIV/AIDS, and hepatitis C, suffer from a variety of symptoms. These symptoms can include pain, shortness of breath, fatigue, bowel or bladder problems, nausea, lack of appetite, and side effects from medications. Palliative care would alleviate this suffering.

Relief from pain is a basic aspect of palliative care; however, skilled pain management is difficult to provide in the community and more challenging in prison. Many prisoners enter the system for drug offenses and have a history of addiction and

thus, prisoners may exaggerate pain. These issues make it difficult for medical staff to know whether patients report pain for their own addictions, to divert to other inmates, or simply to get medical attention. On the other hand, some prisoners may feel that keeping silent about pain is a mark of strength. Rigorous training and oversight are needed to ensure that staff recognize signs of pain and understand protocols for proper medication administration. Despite expectations for pain relief, high levels of uncontrolled chronic pain are present among these prisoners, and clinicians are reluctant to prescribe pain relief. Palliative care is also intended to address emotional, psychological, social, and spiritual needs. Loneliness, depression, anxiety, and fear can accompany serious illness, and alleviating these symptoms is crucial to inmate quality of life. Family support is generally unavailable, and inmates worry about dying in prison.

Prison physicians are primarily responsible for developing and coordinating patient care. In the community, doctor–patient relationships are built on trust and confidentiality. Inmates are less likely to trust physicians, and physicians are less likely to trust inmates, for a variety of reasons. Without this trust, however, honest communication and compliance are less likely. Confidentiality is problematic when inmates receive medical care in the presence of others, such as security guards.

Palliative care is a team project. Nurses, social workers, chaplains, prison wardens, and volunteers may all work with physicians to coordinate support. Teams should identify sources of pain and discomfort, communicate with the patients, plan treatment options, and provide companionship and support. Including security personnel in discussions can expedite movement between prison locations and communication among those involved.

Trained volunteers are a critical part of a palliative care team. Behind bars, these individuals may take the place of family. Where available, strict procedures exist for selecting, training, supervising, and terminating volunteers. Prison volunteers can, at a minimum, sit with and comfort the patient. In some cases, volunteers assist in non-medical activities, such as feeding, dressing, and transporting. They do not, however, provide bathing, toileting, and most hands-on activities. Prison volunteers' activities are limited by prison rules and security concerns.

Prisons are not designed for older individuals and/or those with disabilities; therefore, location of services is a consideration. Whether in medical dormitories, medical centers outside of the prison, or usual housing, accessing needed services, medication, and equipment can be difficult. Older prisoners may feel isolated when they are moved for treatment, and family visits may be more difficult. Environments in specialized locations are better able to provide comfort.

In the community, patients expect to choose their own health-care providers and to have a say in their treatment. This autonomy is not always available for prisoners, raising ethical concerns.

Some level of health care is mandated for prisoners. In 1976, the U.S. Supreme Court decided that prisoners had the basic right to access to care, care that is ordered, and professional medical judgment. One solution to the difficulty of providing health care to chronically ill prisoners is to allow them to leave prison. Compassionate release, part of the Sentencing Reform Act of 1984, is medical parole for extraordinary and compelling reasons. Offenders eligible for release must be 65 years or older, have served 50% or more their sentence, have a chronic or serious condition related to aging that will not improve with treatment, and have substantially reduced ability to function in prison. Allowing more inmates to leave prison at this stage would solve many of the problems of palliative care, but guidelines are vague and appeals rarely successful.

AGING AND OLDER INCARCERATED OFFENDERS, PHYSICAL DISABILITY OF

The United States has the highest incarceration rate in the world, and tougher sentencing policies have resulted in the rise in the number of prisoners who are serving long prison terms. For example, *three strikes* felony sentencing mandates that judges sentence third-time felony offenders to serve long mandatory prison sentences (often 25 years to life), and the punitive sentencing measures associated with the war on drugs of the 1980s and 1990s placed greater emphasis on mandating prison sentences for drug offenders. Furthermore, some states have eliminated parole, which allows for early release for well-behaved inmates. Thus, more people are sent to prison for longer periods of time. Additionally, medical advances allow people to live longer, also contributing to the growth of the number of older prisoners behind bars. Consequently, a large number of inmates are growing old in prison. In fact, older inmates are the fastest growing segment of the U.S. prison population. It is estimated that by 2020, older inmates will make up about one third of the prison population, according to a 2009 article by Tish Smyner and Patricia Burbank. This changing profile, often referred to as *the graying of American prisoners*, creates challenges for prison administrators to develop and modify programs and strategies focused on the special needs of the aging inmate. One of those challenges is delivering health-care services for older inmates. This entry discusses accelerated aging in prison populations, reasons for concern, and challenges.

Accelerated Aging

Although there is no clear-cut consensus, most scholars recommend that correctional agencies adopt age 50 as the chronological starting point for defining older inmates. Because of the unhealthy lifestyles of many individuals before incarceration and the lack of medical care associated with

unhealthy lifestyles, the physiological age of an inmate usually surpasses their chronological age. The physiological age of a typical male inmate is approximately 12 years older than his nonconfined counterpart. Thus, an incarcerated 50-year-old man is likely to be physiologically similar to a 62-year-old man outside of prison.

Prisons currently work under the assumption that incoming prisoners will be young and will still be young when released. Older prisoners have different needs than the rest of the prison population, and, as a result, they need to be treated differently. Most significantly, older inmates (those age 50 and over) require a disproportionate amount of medical attention. In general, aging inmates have more health problems than the general (free) population of the same chronological age. This is due to a combination of two factors. First, prisoners typically come into the prison having led an unhealthy lifestyle and often had limited access to proper health care. Second, the physical environment and the emotional stresses of imprisonment mean that inmates age at a faster rate. This accelerated aging may lead to the need for more medical care. The increased need for health care among older inmates places burdens on already strained prison health facilities.

Why It Matters

One may ask why anyone should care about the medical needs of older prisoners. One reason for concern about the quality of health care in prisons is that the U.S. Supreme Court has repeatedly held that correctional agencies must provide adequate health care for inmates. The Eighth Amendment to the U.S. Constitution protects citizens against cruel and unusual punishment. The courts have held that prisoners retain certain basic constitutional rights, and the Eighth Amendment mandates that correctional institutions provide reasonable health care to its inmates. In *Estelle v. Gamble* (1976), the Supreme Court concluded that deliberate indifference to serious medical needs was unnecessarily inflicting pain and thereby a violation of the Eighth Amendment. The Court ruled that prisoners were entitled to (a) access to care for diagnosis and treatment, (b) a professional medical judgment, and (c) administration of the treatment prescribed by the physician.

In 1998, the Supreme Court also ruled that the Americans with Disabilities Act (ADA) applies in the prison context and that prisoners are entitled to reasonable accommodations for their disabilities under Title II of the ADA. The ADA defines disability as a mental or physical disability that limits one or more major life activities (e.g., seeing, hearing, walking, reading, or concentrating) and/or bodily functions (e.g., neurological, digestive, respiratory, or endocrine functions). The ADA provides disabled inmates equal access to facilities, equal participation in programs and proceedings, and to accommodations within a facility. Older prisoners are not necessarily disabled, but they are far more likely to be or become disabled or to develop conditions that require special accommodation. Thus, disability legislation becomes important when determining whether older prisoner rights are being violated.

Another reason why correctional administrators need to be concerned with the health care of inmates is because most inmates will eventually be released. Many older inmates are released from prison with significantly more health problems than similarly aged individuals in the community. If these inmates have communicable diseases when they are released, they pose a public health issue to the community. Further, inmates released with medical conditions can pose a drain on already constrained resources available for indigent clients (e.g., Medicaid, free clinics, emergency rooms). In addition, inmates who are able to take advantage of prison programs that improve health and cognitive skills or that focus on substance abuse are less likely to recidivate and be rearrested when they return to the community.

Challenges

Older prisoners experience more mental and physical challenges than their younger counterparts. On average, geriatric prisoners have more chronic diseases than adults of similar age living outside of prison, and older inmates will deal with a wider variety of chronic illnesses as they age in prison. Chronic diseases are prevalent among older prisoners and often lead to functional impairments that interfere with daily life. Further complicating the issue is the fact that comorbidities (the presence of one or more disorders

co-occurring with a primary disease) are more commonly found among older inmates than free individuals. It is generally estimated that older inmates experience on average three chronic conditions at the same time. Many of these chronic medical conditions are similar to those also found in the older U.S. population (e.g., chronic obstructive pulmonary disease, arthritis, diabetes, and heart disease, as well as other conditions common to the aging process); however, the prevalence rates are much higher among the incarcerated population. Older inmates may also have conditions that have unusually high prevalence in prison, such as HIV/AIDS and other sexually transmitted diseases, viral hepatitis, and advanced liver damage due to alcohol abuse.

Communicable diseases disproportionately impact inmates largely because the prison environment is ripe for spreading disease. Conditions such as overcrowded living arrangements, delays in medical treatment, limited access to germ-free environments, and prohibitions against the use of harm reduction measures such as condoms and needle exchange increase the probability that infectious diseases will be transmitted from one inmate to another.

Given the fact that aging and chronic illness is progressive, it is inevitable that a number of inmates with these conditions will reach a terminal stage. Older inmates have mortality rates that are 5 times greater for cancer and heart disease than any other age group, according to Brie Williams and Rita Albraldes. Treating a terminally ill individual in prison is difficult at best. Inmates are usually isolated from their friends and family on the outside precisely when they need them most. Terminally ill inmates tend to cycle in and out of infirmaries and hospitals. As their conditions worsen, they will often require around-the-clock nursing services, but most prison health-care systems were not originally designed to provide sophisticated and intensive care to large numbers of chronically ill and/or older inmates. These inmates require a standard of medical care and treatment well beyond that provided to the general inmate population.

Chronic diseases and the natural aging process associated with older prisoners often lead to functional impairments that interfere with daily activities. Functional ability reflects the extent to which

an older person is independent and is measured by assessing a person's need for help with their activities of daily living, which includes bathing, dressing, eating, transferring, and toileting. The prevalence of activities of daily living dependence increases with advancing age and for those with chronic illnesses. Further, the unique activities prisoners face (e.g., climbing on bunk beds, hearing orders from staff, dropping to floor alarms, getting to dining halls for meals) are particularly difficult for older inmates. Thus, a majority of older inmates need a combination of health-care services, assistive devices (e.g., walkers, wheelchairs, hearing aids, and breathing aids), and/or special housing accommodations. Many older inmates require certain physical accommodations that are not easily provided in the typical prison environment. Environmental issues such as limited temperature control, lack of adequate lighting, loud noises, and crowded facilities present problems for older or disabled inmates. Inmates with respiratory problems need to be housed in areas where they will not be exposed to cigarette smoking, for example. Prisoners with spinal cord injuries must be assigned to air-conditioned units. Those with arthritis should not be housed in cold, damp environments. It is important to keep in mind that prisons have been designed with young populations in mind. Thus, the environmental demands of the prison setting can lead to decreased independence among older inmates.

As the older inmate population continues to soar, correctional administrators must consider how prison facilities designed for younger persons can be adapted to accommodate the unique challenges faced by an aging population. Although a significant proportion of older inmates require (and are legally entitled to) medical treatment, they are not necessarily receiving adequate medical care. Several systematic barriers exist that hamper correctional systems' ability to provide adequate health care to its prisoners. One of the greatest challenges is the high cost associated with housing older and infirm inmates. Dealing with a wide assortment of chronic illnesses is not something that most prisons are equipped to deal with from either a medical or cost perspective. The cost for incarcerating a geriatric prisoner is approximately 3–5 times that of younger prisoners, according to Anita N. Blowers, Jennifer M. Jolley,

and John J. Kerbs. It is not uncommon for states to pay US\$70,000 per year for each aging inmate. The high cost is due to higher health-care expenses among geriatric prisoners, including hospitalization, medications, diagnostic tests, and skilled nursing care. In addition, there are substantial custodial costs associated with off-site health care, primarily related to the cost of providing security.

Another obstacle to effective health care is that many correctional institutions lack adequate funding and training to successfully screen new prisoners for diseases and health issues when they first enter the prison. This limits their ability to treat health problems before they worsen. Further, the transient status of inmates who are frequently, and often abruptly, moved from one location to another complicates the health-care screening. Controlling the spread of infectious diseases is challenging if careful screening is not in place. A further complication is that many inmates distrust authority and are reluctant to seek medical attention and cooperate with health-care providers. Lastly, strained resources, pressures to conform to the punitive aspects of command control environments, and lack of staff training may lead to what some refer to as *institutional thoughtlessness*, whereby health care is not necessarily deliberately denied, but other demands divert attention away from identifying the changes that can be adopted to ensure that the health needs of older inmates are effectively addressed. Even when individuals have received adequate health and substance abuse treatment services while in prison, they often face limited access, and insufficient linkages, to community-based health care on release.

As prisons house a larger proportion of aging inmates requiring additional assistance, special physical accommodations, and/or advanced medical treatments, correctional authorities will be mandated to reconsider their way in which they do business. Strategies that correctional systems are beginning to consider include developing separate geriatric prisons, use of telemedicine, and greater use of early release mechanisms, such as compassionate release. Regardless of the strategies employed, correctional systems must be more intentional about recognizing the unique challenges that aging prisoners face and partner with

those in the fields of social work, gerontology, health, and public policy.

most notorious convicts on an island that sat in the middle of San Francisco Bay. Although easily visible, no one was allowed to visit. This denial of access produced rampant speculation about what was going on in a prison that critics began to call America's version of the infamous Devil's Island Prison Colony in French Guiana. Despite no personal contact with inmates or staff (who were required to live on the island), hundreds of stories were generated about escape attempts and the lives of notorious prisoners such as Al Capone, "Machine Gun" Kelly, and Robert Stroud, the so-called "Birdman of Alcatraz."

Alcatraz has been the subject of at least 14 movies. These fictionalized accounts of life on the island first appeared during the 1930s but continue to this day on cable television channels. Among the most widely viewed is the movie *Birdman of Alcatraz* (1962) starring Burt Lancaster as the courageous convict fighting injustice in the federal prison system. (Stroud killed a guard at the federal penitentiary in Leavenworth, KS, and was ordered to spend the rest of his life in solitary confinement.) Another popular film about Alcatraz is *The Rock* (1996), starring Sean Connery and Nicholas Cage. But the movie that perhaps commands the most television time is Clint Eastwood's *Escape from Alcatraz* (1979). The storyline for this film is based on the real-life June 1962 escape by the Anglin brothers and Frank Morris (played by Eastwood) who made it out of the cell house through the ventilator grills in the backs of their cells to the swift currents of the bay. It is not known whether this escape was a real-life success because the three individuals involved were never seen again. These movies have been accompanied by dozens of documentaries about the prison that continue to be made such as *Alcatraz, Living Hell* (2015) on the National Geographic Channel.

In 1975, Alcatraz became a popular tourist attraction when the National Park Service assumed responsibility for the abandoned prison. Since that time, more than 1 million visitors each year have visited the maximum security penitentiary, including the cell houses where they can stand in one of the solitary confinement cells. Some visitors have been able to meet, in person, several inmates who did time on the island during the late 1950s and early 1960s. Unlike most men released from prison, these former inmates seem proud that they

ALCATRAZ

Alcatraz, also known as the *Rock*, was a U.S. federal prison in operation from 1934 to 1963. Alcatraz gained worldwide fascination in part because the Federal Bureau of Prisons housed the nation's

survived life on *the Rock* and that they can tell their stories to tourists.

Included in all the attention that has surrounded this prison were ongoing condemnations by prison reform advocates, some mental health professionals, and a small number of officials from state penal systems. The Bureau of Prisons policy for Alcatraz was based on the assumption that the men who needed to be sent to this unique federal penitentiary were *habitual and incorrigible* offenders who would never abide by societal laws. Thus, inmates remained in isolated cells with limited out of cell time and little time for socialization. Under this policy, no psychologist, educator, or vocational training instructor was ever stationed on the island (i.e., there were no rehabilitation programs). Criticism of a harsh regime that allowed no opportunity—or hope—for reform led to criticism of the Department of Justice for continuing to maintain a prison that one journalist called *America's Torture Chamber*.

A common criticism throughout Alcatraz's 30-year history as a prison is that the Alcatraz regime was psychologically damaging to the mental health of prisoners. To examine this possibility, David A. Ward and a team of graduate students from the University of Minnesota obtained data on the mental health of a one-third sample of the inmate population. This research showed that only about 8% of the inmates had clinically diagnosed mental health problems, were placed on psychotropic medication, or transferred for mental health reasons to the Medical Center for Federal Prisoners in Springfield, MO.

Part of the explanation for this result is that the Alcatraz *convicts* (as they called themselves) had become accustomed to doing hard time as they worked their way up to the Rock through the disciplinary segregation units and solitary confinement cells of other prisons. Furthermore, when they got to Alcatraz, they found an inmate community governed by the *convict code*, which called for prisoners to *do their own time* but always help each other, while remaining united against the staff and the regime. Many of the Alcatraz prisoners had been leaders in other prisons and continued their resistance to the regime at Alcatraz, as evidenced by disciplinary reports, periodic food and work strikes, and legal challenges in federal courts.

Beginning in the 1950s, a movement developed in most of the United States that provided a different justification for imprisonment—rehabilitation—an approach that called for the availability of psychologically based treatment programs and educational and vocational instruction. This movement was particularly critical of a prison whose purposes were punishment and incapacitation. This change in national thinking impacted the Federal Bureau of Prisons, but the status of Alcatraz was also influenced by the 1962 escape by the Anglin brothers and Morris. Also influential was the successful escape in December of that year by John Paul Scott who was able to cut the bars in a room in the basement of the cell house and reach the bay. Using homemade flotation gear, Scott was able to drift with the currents 2.7 miles to the base of the Golden Gate Bridge, where suffering from exposure to the cold air and water, he was rescued by military police who thought he had jumped from the bridge. This escape proved that a prisoner could succeed in reaching the mainland, exposing the vulnerability of the prison that the government claimed was *escape proof*.

As a result of these escapes and the sustained criticism of the purpose of the prison, the federal government decided to close Alcatraz, and by the end of March 1963, the prisoners and staff had been transferred to traditional penitentiaries. The Bureau of Prisons announced the end of the policy of concentrating in one small prison (capacity, 275) the system's most notorious offenders and most violent and escape-prone prisoners. The new policy mandated that problematic inmates be dispersed throughout a number of federal penitentiaries. However, during the 1970s and early 1980s, the dispersal policy failed to provide security for prisoners and staff. In October 1983, after two guards were killed on the same day at a penitentiary in Marion, IL, the bureau returned to the strategy of concentrating the systems' *management problems* in one location. Marion then quickly became known as *the new Alcatraz*. The message that one word—*Alcatraz*—conveys continues today at the bureau's maximum security penitentiary in Florence, CO. Serving as the federal government's current depository for *the worst of the worst* federal lawbreakers (e.g., terrorists, violent gang members),

this prison is now commonly referred to as the *Alcatraz of the Rockies*.

ALCOHOL ABUSE AND CAMPUS CRIME

Crime is best understood as illegal behavior located within the social interactions of offenders and targets in specific social spaces. The contemporary college campus presents a unique set of crime risks. Although serious crime is relatively rare on university campuses, alcohol abuse (the strategic use of alcohol consumption to reach an intoxicated state) is a common practice of some students. College students—many of whom are not yet 21 years old and therefore not legally permitted to consume alcohol—use alcohol intoxication to celebrate events, to lower inhibitions, and to facilitate romantic and sexual encounters. This entry provides an overview of the risks of heavy, episodic drinking on campus; sexual victimization on campus; intimate partner violence; and strategies to reduce the harms related to alcohol abuse on campus.

Risks

Although college students use alcohol to enhance intimate communication and to amplify opportunities for fun and adventure, collective intoxication raises the risk and probability of certain criminal acts. For example, there is an association between alcohol use and violence. Researchers suggest that college students who routinely drink to intoxication are at an elevated risk to be perpetrators and victims of physical violence. As one might expect, campus environments that promote heavy alcohol use are likely to have above average rates of physical assault, vandalism, and public disorder offenses. Furthermore, studies suggest that higher rates of nonviolent property crime are associated with high-risk alcohol use on campus. The association between alcohol use and property offenses may owe, in part, to the fact that campus nightlife draws students away from their homes and property, making them more vulnerable to burglary.

Social drinking events (e.g., house parties, street festivals, tailgating, bar gatherings) may increase the likelihood of criminal victimization for a variety of reasons. A notable crime theory, the routine activities approach, predicts that crime is likely to occur when motivated offenders, suitable targets, and the lack of capable guardianship converge in time and space. A street festival, then, contains significant risk since motivated offenders (e.g., intoxicated, less inhibited partygoers) are competing with other intoxicated students for limited resources (e.g., alcohol and potential romantic and sexual partners) under conditions of relatively low guardianship (i.e., few authority figures present to discourage conflict). The combination of intoxicated students competing for resources in a context lacking in social control can result in physical altercations and aggression.

Sexual Victimization

One of the greatest crime risks on college campuses is the risk of sexual victimization in the drinking scene. This particular form of victimization has received much attention in recent years from students, parents, activists, celebrities, filmmakers, and politicians. Research suggests that as many as one in five college women will be a victim

of sexual assault during her college years. However, measures of the rate of sexual victimization among college students have been subject to scrutiny. The definitions of rape and sexual assault researchers employ can influence their measurements, and critics have questioned the validity of the definitions used in some of the most prominent studies of the early 2000s. Still, even more conservative estimates suggest that sexual victimization on college campuses is a widespread social problem.

Since sexual victimization often occurs in the college drinking scene or following a drinking event, questions surrounding the way students perceive the relationship between alcohol and sex have emerged as central to the issue of sexual victimization on college campuses. Just as with other campus crimes in the drinking scene, sexual victimization often occurs in the context of motivated offenders competing with other students for limited resources (in this case, sexual partners) with few capable guardians present. Given that victims in many cases are intoxicated in campus sexual assaults, research suggests that offenders may seek to identify heavily intoxicated individuals who they perceive to be the most suitable targets. To further compound this problem, research has found that a significant percentage of rapists become repeat offenders, thus suggesting that many offenders go undetected by law enforcement.

Efforts to reduce these crimes have pointed to *hookup culture* as contributing to the unique risks of sexual victimization in the campus drinking scene. Hookup culture includes the norms, rituals, language, and social practices that guide the casual romantic or sexual coupling that emerges out of the campus party scene. One major component of hookup culture on campuses is that it is normative for students to use alcohol as a means to lower their inhibitions and become more comfortable with having sex with the people they meet or spend time with at parties, bars, or other drinking events. Furthermore, students may be encouraged or pressured by their cohorts to find sexual partners while in the drinking scene and to have sex with those partners while intoxicated. This clearly poses a challenge to identifying and preventing sexual victimization in the drinking scene as many of the

previctimization warning signs can appear to be normal interactions between consenting adults. The effectiveness of perhaps the most prominent programming effort to reduce sexual victimization on campus—bystander intervention training—is especially challenged by the norms of hookup culture.

Bystander Intervention Training

Bystander intervention training typically aims to teach students how to recognize previctimization warning signs and, in situations they perceive as risky, to intervene to prevent an assault from occurring. However, the norms of the college drinking scene may often impede intervention. Students may be unsure if a perceived potential offender intends to cause harm, if a perceived potential victim is in need of assistance, or which strategy they should employ to mitigate risk after it is identified. This uncertainty may be amplified when the potential bystander is intoxicated. Some movements to reduce sexual victimization, however, have drawn attention to the aspects of campus drinking culture and hookup culture that contribute to the perpetuation of myths about sexual assault. For example, many activists have sought to raise awareness about factors that preclude consent (e.g., if the victim is intoxicated, if the victim has been coerced). Activists have also sought to challenge victim-blaming tactics (e.g., asking how much the victim had to drink, asking what the victim was wearing) and to discredit exaggerated claims of high rates of false reporting.

Sexual victimization has become a major concern for campus safety officials and a significant consideration for university public relations and recruitment practices. Although debates over the prevalence of the problem continue, so do criticisms of institutional responses to it. Attempts to confront this issue have emerged in music, film, political statements (including statements from President Barack Obama), and other mediums. However, although sexual victimization in the college drinking scene has received a great deal of attention in recent years, other forms of interpersonal victimization have largely gone unacknowledged.

Intimate Partner Violence

One of the least acknowledged and least studied forms of campus victimization is intimate partner violence. Intimate partner violence on campus may also be connected to the norms and rituals that produce, and are reproduced by, the college drinking culture. This form of violence is distinct from other types of crime due to the ongoing relationship and shared lives of the victims and perpetrators. This unique context makes it less likely that victims will contact police and more likely to be underreported. Even so, relationship violence has been found to be a prevalent problem among college dating partners. This includes psychological, sexual, and both minor and severe physical violence. Research suggests that more than 20% of college women have experienced sexual or physical abuse within a dating relationship. Further, the problem of dating violence is worsened by the consumption of alcohol.

The college drinking culture functions to create more motivated offenders, as well as more suitable targets, of relationship violence. Investigators in the field of intimate partner violence have reported alcohol use as a consistent characteristic of men who abuse their partners. Additionally, studies have found that heavy drinking and illicit drug use are risk factors of relationship violence victimization. Perpetrators of abuse may be more likely to commit violent acts against their partners while intoxicated due to the perceptions of what college students consider acceptable behavior while intoxicated. For example, an intoxicated perpetrator's violent behavior may be excused by both the target of the crime (in this case, the relationship partner) and by any potential capable guardians because the alcohol is perceived as the cause of the violence instead of the perpetrator. Victims of relationship abuse who point to alcohol as the source of their partner's abusive behavior may be more likely to stay in the relationship, thus leading to further victimization. Although the connection between risk of victimization and alcohol consumption is less clear, it is possible that intoxicated partners are more suitable targets of violence because they are not as capable of defending themselves. Victims of abuse may be more likely to use alcohol as a coping mechanism, which can in turn lead to reoccurring victimization.

Alcohol consumption on the victim's part may lead capable guardians to blame the victim for their abusive partner's behavior, leading to a decrease in social support for the victim. Additionally, because surveys on the effects of alcohol consumption have revealed that many college students report having been in an argument while intoxicated, arguments between partners that are psychologically or verbally abusive may go unrecognized as abuse by both capable guardians and by victims. Bystanders may assume that a couple arguing at a social event in which alcohol is present is insignificant and therefore not appropriate for intervention. As the presence of social support has been found to increase the chances of a victim exiting an abusive relationship and lead to more positive mental health outcomes for victims, the role of alcohol may worsen the effects of relationship abuse on victims. Further, the college drinking culture can lead to an increase in social support for abusive partners, and their behaviors may be excused or even viewed as acceptable by peers who blame the intoxicated victim. The specific context of the college drinking scene has the potential to motivate more perpetrators of relationship abuse, create more suitable targets of intimate partner violence, decrease the likelihood of a capable guardian intervening, and exacerbate the consequences of being a victim of relationship abuse.

Combating Risks

In summary, there is a clear relationship between alcohol use and some forms of criminal victimization in campus life. As seen through the lens of the routine activities approach, the less inhibited—and sometimes chaotic—nature of collective intoxication temporarily increases the pool of motivated offenders and raises target suitability. College drinkers often report feeling less committed to prosocial norms when they are intoxicated and are more likely to behave in aggressive ways that are less socially acceptable in the sober interactions of everyday life. Furthermore, the college drinking culture promotes behavioral patterns that reduce capable guardianship. For example, the social drinking script includes the potential for spontaneous (or loosely planned) sexual coupling encounters during a drinking episode. These

encounters may result in intoxicated students leaving a social event together. When intoxicated students physically separate themselves from sources of social support and capable guardianship, the potential for coercive sexual encounters increases. Moreover, research suggests that college drinking culture provides systematic absolution for students who exhibit antisocial behavior while under the influence of alcohol. Thus, college drinkers may be less likely to hold one another accountable for aggressive acts (e.g., physical violence or verbal hostility toward intimate partners) if they interpret the behavior as temporary, episodic, and caused by alcohol consumption.

Campus life administrators can combat the constellation of risks presented by college drinking culture by educating incoming students about the dangers existing in routine social practices, by implementing a campus-wide bystander intervention initiative, by holding students accountable for the criminal acts they commit on campus, and by generating a campus discussion around the best practices for identifying and reporting sexual victimization and intimate partner violence on campus.

ALCOHOL AND AGGRESSION

Interpersonal aggression is typically defined as a behavior that is directed toward another individual with the intent to cause harm. The perpetrator acknowledges the act may inflict harm on the victim, and the victim is motivated to avoid the incident. Harm in this definition can encapsulate various types of harm, including emotional, psychological, or physical harm. This definition is sufficiently broad in scope as to include indirect aggressive behavior, such as relational and verbal aggression, as well as more physically aggressive acts, such as violent threats or assault. Also imbedded in the definition is the requirement that the behavior be carried out with the intent to cause harm regardless of the actual outcome.

Violence is considered to be a more severe form of aggression in which harm is intentionally inflicted. Absent from the literature is a description of the point at which an aggressive act is considered a violent act. There are behaviors that are clearly violent (e.g., murder, physical assault); however, there are other cases (e.g., uttering threats to cause harm, attempted robbery) whereby the distinction is less clear and classification is more challenging. Evident from these definitions is that all violent behavior can be categorized as aggressive; however, not all aggressive behavior is violent.

Furthermore, in the extant criminal psychology literature, behavior liable to be punished by the courts (e.g., convictions for assault, kidnapping, robbery) is violent behavior classified as a violent crime. Conversely, other harmful behavior that is primarily psychological or emotionally damaging in nature (e.g., name calling, spreading rumors) is

not typically punished by the courts and is more commonly deemed to be aggressive behavior. A violent crime can range from a physical assault in a bar context, a serious aggravated assault, robbery with a firearm, sexual assault, or, most severe in outcome, a homicide. Interpersonal aggression and violence have been studied from various theoretical perspectives and are understood to be influenced by numerous environmental, social, neurobiological, and cultural factors.

Substance use, particularly the consumption of alcohol prior to the perpetration of a violent incident, is well-documented as a significant risk factor for violence. Numerous epidemiological, cross-sectional, and experimental studies have investigated and established the positive relationship between alcohol use and violence. This entry begins with an overview of the prevalence of alcohol-related violence and some of the key risk factors for this subtype of violence. The entry concludes with a discussion of an intervention framework for individuals involved in alcohol-related violence.

Prevalence

In terms of prevalence, the influential research of Kai Pernanen examined the presence of alcohol in episodes of violence and reported alcohol use in 42% of violent incidents. Other studies identified alcohol as an influencing factor in as many as 60–85% of violent incidents. The exact proportion may vary by jurisdiction, definition of violence, and the sample of offenders involved. However, what has been consistently reported is the positive association between alcohol and violence and that a large proportion of violent crime involves alcohol use.

Violent crime negatively affects not only the victim but also the victim's family, the community at large, and the perpetrator of the violent act. Alcohol-related violence has significant social and economic costs, so a complete understanding of its precursor or underpinning is important.

Despite alcohol use being implicated in violent behavior, the majority of individuals who consume alcohol are not violent. Acute alcohol consumption rather than chronic alcohol abuse has been suggested to be more strongly associated with individuals incarcerated for a violent offense. However, neither acute alcohol use nor chronic

alcohol abuse is sufficient for aggression to occur because many drinking episodes do not result in violence, and some acts of violence do occur without the influence of alcohol. Therefore, the following question remains: What factors influence the relationship between alcohol use and aggression?

Various individual, environmental, cultural, and situational factors influence the strength of the relationship between alcohol and aggression. Examples include dispositional aggression personality disorders, impulsivity, problem-solving ability, and cognitive functioning. The following is an overview of some of the key risk factors involved in alcohol-related violence.

Risk Factors for Alcohol-Related Aggression

Dispositional/Trait Aggression

Decades of research examining laboratory-based aggression measures to assess the effects of alcohol use on aggression have established that alcohol consumption increases the likelihood of reacting aggressively when individuals are faced with provocation. A key component that has been shown to interact with aggressive response and alcohol consumption is dispositional aggression. Alcohol increases aggressive responses in individuals with a high disposition for aggression; however, alcohol does not have the same influence on those individuals with a low disposition for aggression.

Alcohol-Related Outcome Expectancies

Within the framework of social learning theory, violence and aggression, similar to many other behaviors, are learned by observation and imitation of others. Developmentally, behaviors are learned through observing the positive (reinforced) and negative (punished) consequences of behaviors. An individual's violent behavior is developed from previous observational and experiential learning that aggression is rewarding. As such, the positive expectancies associated with aggression increase the likelihood of engaging in such behavior; consequently, the co-occurrence of alcohol consumption and aggression influence the likelihood of violence in a given scenario. That is, through experience and observation, individuals

learn the association between drinking and becoming violent (i.e., "When I/others drink at the club, I/others always get in a fight."). This expectation can be based on previous observations or from personal experiences of getting into bar fights.

Research shows that this cognitive representation of previous experiences shapes the outcome of future situations. Those who believe that alcohol makes them violent or those who expect violence in a specific type of context (e.g., drinking at a pub or bar) are more likely to become violent than those who believe otherwise. Trait aggression has been reported to influence this relationship further, in that the positive outcomes for aggression are more potent for those who have high trait aggression than for those who have low trait aggression. Alcohol-related outcome expectancies are not the only persuasive factor manifesting the positive relationship between aggression and alcohol; however, challenging these negative outcomes may assist in decreasing alcohol-related violence.

Social Problem Solving, Cognitive Processing, and Impulsivity

The literature on alcohol use, aggression, and the interrelationship of these variables with other influential factors, such as impulsivity and problem solving, is complicated, and a comprehensive review is out of the scope of this entry. However, a few points are worth addressing, specifically with respect to the interplay among aggression, alcohol use, and cognitive processing. For instance, physiologically these variables interact under a few conditions. The first condition is when a low amount of alcohol is consumed, this may reduce inhibitory factors and thus facilitate aggression. At low doses, alcohol alters the anxiety–threat system by decreasing anxiety and inhibition. In a situation in which individuals are threatened or provoked, they are disinhibited (i.e., more impulsive) and may therefore be more likely to respond with an aggressive act than they would had they not consumed alcohol.

The second condition occurs under a large amount of alcohol consumption; this may cause a sedative or analgesic effect that alters the cognitive–control system. Under this similar condition, high levels of alcohol consumption also impair one's ability to make judgments, which may also

lead to aggression. Social problem solving and cognitive functioning are disrupted, and individuals may have alcohol myopia, which can be best described as having tunnel vision in relation to the perceived provocation; individuals only attend to the most salient and proximal elements of a social situation, such as the provocation, and problem solving and abstract reasoning are disrupted. Individuals fail to implement problem-solving skills, such as identifying the consequences of their action (e.g., potential conviction for a violent assault) or alternative and nonviolent responses to the social interaction. Therefore, alcohol consumption by individuals with information-processing deficits is purported to possibly increase the risk for aggression.

In a 1997 review, Stephen Chermack and Peter Giancola noted the association between information-processing deficits and aggression as well as the ability of alcohol to disrupt executive cognitive functioning and problem solving and to limit abstract reasoning. Therefore, alcohol consumption by individuals with information-processing deficits may increase the risk for aggression. As a result, alcohol abuse has been suggested to be a potential mediating variable in the association between impulsivity and aggression.

With the frequency of impulsivity and violent behavior considered, acknowledging the effect of an impulsive personality in the relationship between alcohol use and aggression is important. In general, alcohol abuse is a complex behavior that is not innately impulsive. However, if impulsivity is related in some way to alcohol use, one would expect individuals who exhibit impulsive behavior to have high rates of substance use, and research has shown this to be the case in various offender, nonoffender, and clinical samples.

Other findings provide further support for this relationship. In a longitudinal study of delinquents and violent offenders, individuals who scored high on impulsivity and hyperactivity measures were found to be 3 times more likely to develop an alcohol problem by age of 25. Furthermore, individuals high on impulsivity and alcohol problems were 10 times more likely to be arrested for a violent offense than those individuals who did not exhibit impulsivity or alcohol problems. Evidently, results indicated that delinquents who are impulsive and drink heavily are most likely to be violent.

The aforementioned research suggests the positive relationship among alcohol use, social problem-solving deficits, impulsivity, and aggression. Given that these are key areas of influence, they are worthy starting points for consideration in developing treatments for alcohol-related violence in offenders.

Interventions

The intended treatment targets of cognitive behavioral treatment programs for violent offenders typically aim to decrease antisocial attitudes and cognitions related to violence. Often, these are contextualized and situated within an anger management framework. Given that substance use is an important criminogenic need, naturally, the role of substance use should be addressed within the context of a violent offender treatment program; however, it is seldom the focus despite its strong prevalence in violent offenses. Notably, specific interventions designed to control and treat alcohol-related violence are limited.

Mary McMurrin, a key researcher and clinician in the treatment of alcohol-related violence in the United Kingdom, is an advocate of advancing the development and implementation of programs addressing this specific need area. McMurrin has devised a comprehensive therapeutic model of alcohol-related aggression, which is called the Control of Violence for Angry Impulsive Drinkers model. This framework includes the key cognitive behavioral treatment-based elements of anger management and problem solving; however, it also aims to address the treatment targets of greatest relevance to alcohol-related violence. A few of these targets include modifying drinking habits, weakening beliefs about the effects of alcohol, managing aspects related to cognitive and behavioral impulsivity, and enhancing problem-solving skills. Given that the program offerings in this domain are limited, assessing the outcomes related to programs, such as the Control of Violence for Angry Impulsive Drinkers, merits further attention.

The relationship between alcohol and aggression is complex, and researchers have been limited in their capacity to demonstrate a direct causal relationship between these factors. However, consistent evidence has illustrated a

connection, with the recognition that the role of indirect causes, such as individuals' differences and situational factors, is important. In addition, associations among high trait aggression, impulsivity, deficits in social problem solving, and alcohol-related outcomes expectancies have been shown. Finally, although correctional programs specifically addressing the specific antecedents of alcohol-related violence are limited, considerable research has been conducted to help unravel the complex relationship involved and enrich knowledge and understanding of alcohol-related violence.

AMERICAN CORRECTIONAL ASSOCIATION

The American Correctional Association (ACA) is a professional membership organization composed of individuals, agencies, and organizations that are involved in all facets of the corrections field, including adult and juvenile services, community corrections, probation and parole, jails, and prisons. The association has thousands of members as well as more than 100 chapters around the world and affiliates representing states, professional specialties, and university criminal justice programs. The ACA has been a driving force in establishing national and international correctional policies and advocating safe, humane, and effective correctional operations. It also disseminates the latest information on correctional policy and standards to members, policymakers, individual correctional workers, and departments of correction. This entry first reviews the history of ACA and then discusses ACA's standards, particularly with regard to community corrections programs, special populations, and correctional health.

History

In 1870, an assembly of leaders in U.S. and international corrections held a meeting in Cincinnati, OH. After electing Rutherford B. Hayes,

then-governor of Ohio and future U.S. president, as the first president of the association, the leaders then developed principles stating the beliefs and values underlying the practice of the corrections profession. As a result of this meeting, the National Prison Association was founded, an organization that subsequently evolved into ACA.

ACA continued in the spirit of its founders when it renewed and revised these principles in 2002. Since then, ACA's principles of humanity, justice, protection, opportunity, knowledge, competence, and accountability have guided corrections practices, with the cooperation and support from leaders of local, state, national, and international communities and organizations.

Community Corrections Programs

ACA standards for community corrections programs are designed to provide community corrections professionals with the tools to identify and address offender needs and provide effective offender programming and services. The purpose of the standards is to help introduce effective practices in community corrections programs, in order to create a safer community, through the reduction of recidivism.

Two examples of expected practices applicable to Adult Probation and Parole Field Services (APPFS) are APPFS-1B-06 and 4-APPFS-2A-02. Under APPFS-1B-06, probation officers should consider sentencing alternatives that match offender characteristics and needs and balance those needs with the primary mission of public safety. As stated in 4-APPFS-2A-02, each agency should establish an objective assessment process that identifies offender programming needs, risk of reoffending, and level of supervision. The assessment process should include the following:

- an initial assessment of each offender using a standardized and validated assessment tool
- additional assessments or evaluations
- personal interview with the offender
- development of objectives that address community safety and offender needs
- assessment or reassessment results recorded in the case file and communicated with the offender

Special Populations

ACA also recognizes the importance of having standards that address the distinctive needs of the special populations constituency. Because individuals with special needs have increased vulnerability, they require specialized care. The functional deficits associated with intellectual disability, for example, create particular vulnerabilities and habilitation needs. With rates of intellectual disability in state and federal prisons ranging from 0.5% to 20%, depending on the method of assessment, there is a need for specialized services that provide assistance in adaptive functioning and prison adjustment.

In 2012, about one in every 35 adults in the United States, or 2.9% of adult residents, was on probation or parole or incarcerated in prison or jail. Based on these rates, an estimated one out of every 20 people will spend time behind bars during their lifetime, and a significant percentage of those will be individuals with mental illness. In fact, individuals with severe mental illness are 3 times more likely to be in a jail or prison than in a mental health facility, and 40% of individuals with a severe mental illness will have spent some time in their lives in either jail, prison, or community corrections. With about 20% of prison inmates having a serious mental illness, and 30–60% having substance abuse problems, the prison and jail systems have become major mental health facilities. Accordingly, ACA, through its standards, training, and accreditation process, insists that correctional agencies provide appropriate treatment to inmates with serious mental illness, including substance use disorders.

Two examples of special needs-related standards that are applicable in adult correctional institutions are 4-4374 Mental Illness and Developmental Disability and 4-4377 Management of Chemical Dependency. Standard 4-4374 states that offenders with serious mental illness or a severe developmental disability are to receive a mental health evaluation and, where appropriate, referred for placement in noncorrectional facilities or in units specifically designated for handling this type of individual. For offenders with chemical dependency, Standard 4-4377 indicates they should have access to substance disorder information, education, and/or treatment programs. Such

substance use disorder treatment programs should include the following:

- a standardized needs assessment administered to determine the level of substance use treatment needs and criminogenic risks/needs
- an individualized treatment plan developed and implemented by a clinician or multidisciplinary team with appropriate training, and certification or licensure (where required by statute), in substance use disorders treatment
- prerelease education related to the risk of return to substance use
- program participant involvement in aftercare discharge plans

Correctional Health

A critical entity within ACA's organizational structure is ACA's Office of Correctional Health (OCH). This office serves ACA members, jurisdictions, and affiliates by supporting health services programs for the effective delivery of health care to offender populations. To help correctional facilities provide security and quality care for the offender population, OCH offers training for correctional health professionals; needs assessment and technical assistance; and comprehensive services, support, and resources. The department also is responsible for the development, improvement, and promotion of ACA's performance-based health-care standards and the health certification program.

The performance-based standards, expected practices, and outcome measures—developed in collaboration with health care, behavioral health, and security professionals—are available to all adult and juvenile agencies. Compliance with the standards and expected practices serves as the basis for the health services accreditation program, the goal of which is to improve the delivery of health and behavioral health care to offenders within the correctional environment.

OCH also contracts with a correctional behavioral health expert to provide technical assistance and consultation germane to ACA's behavioral health-care performance-based standards, expected practices, outcome measures, and accreditation process. In addition, OCH is responsible for all treatment committees (health care, mental

health, and substance disorders committees) and the Coalition of Correctional Health Authorities. Coalition of Correctional Health Authorities was founded on the idea of bringing together the health authorities to exchange exemplary practices in correctional health and clinical updates, to learn new and improved techniques in quality health-care delivery, to address critical emerging issues, and to network.

Moreover, OCH offers programs that address the learning needs and interests of the members of the correctional health-care team. At ACA's conferences, OCH not only provides educational programs to improve the knowledge, skills, and abilities of correctional health and behavioral health professionals but also offers networking opportunities. In addition, ACA expands learning opportunities utilizing a variety of formats, such as online courses, webinars, and customized on-site training.

AMERICAN GANGS

American street gangs first emerged in the late 18th century when large groups of immigrants migrated to the United States. Upon arriving in America, immigrants felt isolated and alone due to language and cultural barriers. To overcome these barriers, immigrants banded together along racial, ethnic, religious, and cultural backgrounds. These groups provided cultural support, enhanced communications, and protection from persecution by more established groups of American residents. Some of the first groups to emerge in California and New York formed along Chinese, Irish, Italian, and Jewish ties.

As the immigrant groups grew, rivalries were inevitable. Territorial turfs were established, and the emerging immigrant groups were willing to fight and die to preserve their territory and way of life. Over time, some groups gained reputations for violence, thus creating the foundations for the first American street gangs.

Immigrant gangs also became fertile opportunities for criminal activity such as bootlegging, drug trafficking, prostitution, and smuggling. Once the gangs grew, they engaged in more violent crimes. Extortion, assault, battery, arson, robbery, rape, and murder were natural consequences of the gangster lifestyle. This process continues today as the United States experiences continued growth in gang-related crime and criminal gangs.

This entry addresses differing statutory definitions of criminal gangs, the magnitude of gang membership, gang classifications, and major reasons why an individual joins a gang.

Definition of a Criminal Street Gang

Although the federal government and all 50 states have gang-related criminal statutes, there is no single, uniform definition of what constitutes a criminal gang. However, most federal and state statutes define a criminal street gang as:

- (1) a group of three (sometimes four or five) individuals or more;
- (2) who routinely engage in a pattern of gang-related criminal activity; and
- (3) self-identify the gang with a common name, sign, or established leadership.

Definitions of what constitutes gang-related criminal activity also differ. Most frequently, the federal and state statutes itemize a laundry list of certain property and personal (violent) crimes that, if committed on behalf of a gang, constitute gang-related criminal activity. These crimes generally include murder, rape, robbery, burglary, arson, aggravated assault, battery, grand larceny, and other property crimes.

Definition of a Prison Gang

The federal and state governments also differ as to what constitutes a prison gang. However, most federal and state statutes define a prison gang as:

- (1) a group of three or more inmates that band together;
- (2) that are ready to fight, commit crimes, or disobey prison rules for advancement and preservation of the prison gang; and
- (3) present a threat to rules, regulations, or authority of the correctional facility.

The prison gang is a disruptive group of inmates that pose a threat to the protection and security afforded by correctional facilities.

Magnitude of the Gang Pandemic

Criminal street gangs exist in all states, all large cities, and on most tribal lands. According to the 2011 National Gang Threat Assessment, more than 33,000 gangs, with an estimated 1.4 million gang members, exist in the United States. These numbers continue to grow.

The Assessment further reveals that criminal street gangs are responsible for an average of 48% of violent crime in most jurisdictions. This statistic spikes to 90% of all violent crimes in some major cities. Consequently, criminal gangs are major forces that threaten national security not only in small foreign countries but also in many U.S. cities.

Some of the largest and most violent gangs in the United States include the Almighty Latin King Nation, Aryan Brotherhood, Barrio Azteca, Bloods, Crips, Hells Angels MC, Mongols MC, MS-13, the Mexican Mafia, Ñetas, Norteños, Nuestra Familia, Outlaws MC, Sorteños, Zetas, and the 18th Street Gang. The membership of some criminal gangs is greater than that of a small country. These gangs include:

- Crips, with more than 35,000 members;
- Nuestra Familia, with more than 42,000 members;
- Latin Kings, with 50,000 members; and
- 18th Street Gang, with more than 50,000 members.

MS-13 is a large transnational gang that routinely plans and controls criminal activity in one country that is carried out in another country. It is estimated to have more than 70,000 members. As such, it is considered a threat to national security not only in Mexico and Central American countries but also in the United States.

Gang Classifications

The 2011 National Gang Threat Assessment provides five major classifications of gangs. The classifications include:

- (1) neighborhood gangs,
- (2) criminal street gangs,
- (3) one-percenter outlaw motorcycle gangs (OMGs),

- (4) prison gangs, and
- (5) transnational gangs.

Unfortunately, these classifications blur. For example, neighborhood gangs are becoming more sophisticated, more organized, and more adept at using the Internet and cell phones to commit crimes. With increased mobility and improved communications, traditional neighborhood gangs become more aggressive and broaden their territory, quickly evolving into criminal street gangs.

Sophistication also opens the door to organized forms of gang-related criminal activity. Mexican cartels, transnational gangs, and organized crime syndicates readily create alliances with traditional neighborhood gangs and criminal street gangs when it serves to strengthen drug trafficking routes or enhance other gang-related criminal enterprises. As a result, there is no clear line of demarcation when it comes to gang classifications. However, these gang classifications do provide a basic foundation that facilitates uniform analysis of gang growth, gang membership, and gang-related criminal activity.

Neighborhood Gang

The term *neighborhood street gang* denotes a gang that is small in terms of gang membership, geographic territory, and gang-related criminal activities. Criminal opportunity is often individualistic and opportunistic, limited primarily to drug possession, small sales of drugs, assault, battery, and miscellaneous property crimes. On occasion, the neighborhood gang may transact business in adjacent towns or cities, but generally, the territorial turf is relatively small. For the most part, the neighborhood is created to provide a sense of belonging and protection that includes small profits derived from a few gang-related criminal activities.

Criminal Street Gang

The criminal street gang focuses more on profits derived from gang-related criminal activity. Ever evolving, it often lacks the leadership and sophisticated organizational structure associated with organized crime, drug cartels, or

transnational gangs. Gang-related criminal activities consist primarily of extortion, assault, battery, property crimes, prostitution, and low-level drug dealing. As the gang grows, the criminal activities and territorial control expand. When this occurs, the street gang is likely to make alliances with other gangs or drug cartels that serve to further gang-related criminal operations.

Prison Gang

As noted, a prison gang operates within the confines of correctional facilities. Newly formed prison gangs emerge when inmates band together for support, a sense of belonging, and mutual protection. The prison gang replaces a feeling of isolation and fear of being violated by predatory inmates. Most often, prison gangs form along racial, ethnic, cultural, or geographic backgrounds, thus serving to strengthen solidarity of and loyalty to the prison gang.

OMGs

The Bureau of Alcohol, Tobacco, Firearms and Explosives defines an OMG as any group of motorcyclists who voluntarily band together, abide by and enforce the OMG's rules, and engage in gang-related criminal activities that bring members and the OMG into repeated and serious conflict with society and the law. To qualify as an OMG, the motorcycle club must be (a) an ongoing organization of three or more persons (b) with a common interest and/or activity (c) characterized by a pattern of gang-related delinquent or criminal conduct.

Transnational (International) Gang

In contrast to small neighborhood gangs, transnational gangs are larger, well organized, and highly sophisticated. By definition, the transnational gang routinely plans and organizes gang-related criminal activities in one country that are executed in another country. As such, the transnational gang is a powerful criminal organization, if not a crime syndicate, that often participates in weapons smuggling, extortion, and international drug trafficking activities.

As evidenced, gang classifications tend to blur and overlap. For example, prison is a revolving door for many neighborhood or street gang members. While incarcerated, street gang members often join a prison gang for protection. The prison gang member frequently returns to his or her former street gang upon release. This serves to place the tentacles of prison gang power and control directly into criminal street gangs. It also provides a never-ending supply of new recruits for the prison gang when the street gang members are incarcerated for gang-related crimes.

Common Reasons Why Someone Joins a Gang

Criminal gangs differ in nature and composition. As such, the psychological underpinnings for joining different types of gangs may vary according to the geographic and socioeconomic background of each individual gang member. However, the most frequently given reasons for joining or remaining in a gang are as follows:

- a sense of belonging, connectedness, and companionship;
- desire to enhance self-esteem, self-identity, and respect;
- money to survive and/or enhance perceived social status;
- protection against victimization;
- a feeling of power or control;
- access to drugs, alcohol, and sex; and
- fear of retaliation for leaving the gang.

The sense of belonging, protection against victimization, and status are key factors for joining a gang. The new gang member gains a feeling of security and self-esteem, knowing that the entire gang will back him or her up if threatened by a non-gang member. The gang becomes the gang member's new way of life, if not the gang member's entire life.

Idle Time

Geographical access to gang members is a key factor to consider when determining the likelihood of joining a criminal gang. However, other

factors, such as idle time and boredom, also affect the likelihood of joining a gang. Some additional factors may include:

- lack of opportunities for employment;
- lack of social opportunities;
- lack of close family ties;
- lack of close friends or associates;
- lack of supervision; and
- lack of attachment to school, organized sports activities, or church groups.

Essentially, an overall lack of attachment, weakened social bonds, and excess idle time seem to be common denominators when determining the likelihood of joining a gang.

Positive Reinforcement of Antisocial Behavior

Gang members are duty bound by an oath of loyalty to fight or kill anyone who disrespects or threatens the gang or a fellow gang member. In addition, rival gang members are perceived to be subhuman threats, similar to the threat of an insect. This dehumanization process further serves to desensitize and justify the use of violence. Combined, gang-related criminal activity and acts of violence serve to positively reinforce solidarity and loyalty to the criminal gang.

Similarly, group willingness to commit criminal acts of violence diffuses and minimizes individual responsibility and accountability. When more than one gang member commits a crime or participates in a fight, accountability for the act is diffused, and the individual gang member feels less blameworthy. This sense of belonging and lack of individual responsibility further perpetrate antisocial behavior and the gangster lifestyle.

In summary, criminal gangs are a growing concern in the United States. They are becoming more sophisticated, using modern technology, the Internet, and interstate highways to conduct gang-related criminal activities of a larger magnitude and more geographic in scope. Due to the rapid growth of gangs and gang members, they present serious national security concerns to many foreign countries as well as the United States.

AMERICA'S MISSING: BROADCAST EMERGENCY RESPONSE (AMBER) ALERT

The America's Missing: Broadcast Emergency Response (AMBER) Alert system was created after the abduction and murder of Amber Hagerman in 1996. AMBER Alerts are police-issued notifications providing information (e.g., about the abductor's car, the child's name, the child's last known location) to the public in order to help locate a missing child and abductor. Alerts were intended for stranger abductions but are most commonly used in cases of familial abductions or other missing-child circumstances. AMBER Alert research branches into the fields of criminology, law/policy, and psychology. This entry discusses

these fields as well as a psychological analysis and the future directions of research.

Effectiveness of AMBER Alert: A Criminological Analysis

Criminologists have discovered a number of key themes related to the limited effectiveness of the AMBER Alert system. First, most AMBER Alerts have no effect. Even when they are allegedly successful, they do not appear to routinely save lives. Furthermore, even when AMBER Alerts are in fact successful, it is typically not in clearly life-threatening circumstances. The so-called success cases overwhelmingly involve parents, other family members, and other categories of offender not suggestive of the stereotypical abductors or abductions that the Alert system was designed to address.

Second, most AMBER Alert success cases involve recovery times usually much longer than 3 hr—a crucial consideration in light of research showing that most child abduction–murder victims are dead within that timeframe. Of course, an important caveat in interpreting AMBER Alert case outcomes is the impossibility of knowing what would have happened in any particular AMBER Alert case had no Alert been issued. Even so, it is still possible to reasonably speculate on the likely threat posed. One study found no statistically significant differences along measurable factors between Amber Alert success cases versus cases in which the Alert had no effect. This suggests that the unmeasurable factor of actual threat was comparable—and minimal—for both categories of cases.

Another major theme emerging from AMBER Alert research is the unavoidably conflicting imperatives of rapid issuance and the provision of accurate and authentic information. One study found that the intuitively plausible issuance criteria of *peripheral harm* (i.e., harm committed by the abductor against someone other than the child) is ironically indicative of less threat to the abducted child. This finding was driven by the identity of most abductors in AMBER Alert cases (parents and/or other family members) who can usually be presumed to pose no immediate threat to the child regardless of their hostility to other parties. In short, evidence suggests that AMBER Alerts,

although well intentioned, are not particularly effective at addressing their intended purpose of rescuing children from stranger abductors.

AMBER Alert as Crime Control Theater (CCT): A Policy Analysis

Some policy scholars have classified AMBER Alerts as CCT, a term used to describe legal actions that appear to work but are actually ineffective. Four criteria determine whether a legal action can be classified as CCT: (1) the legal action was a response to moral panic, (2) the legal action receives unquestioned promotion and acceptance, (3) the legal response relies on mythic narratives, and (4) the legal action is an empirical failure. Some researchers have classified the AMBER Alert system as CCT because it meets all of these criteria. For instance, AMBER Alerts were created after the abduction–death of Amber Hagerman, which sparked widespread moral panic about child abductions. Moreover, few people question the effectiveness of AMBER Alerts. Lawmakers and the public often strongly support the AMBER Alert system. AMBER Alerts also appeal to mythic narratives in that they target the stranger danger narrative within society. Finally, AMBER Alerts are empirical failures and are rarely effective in saving children from stranger abductions.

Overselling AMBER Alert: A Psychological Analysis

Certainly, rescuing abducted children is an important endeavor, and even legal actions that are little more than symbolic can serve an important purpose (e.g., communicating that lawmakers are doing something, communicating norms that abduction is a serious crime). Even so, legal scholars have expressed concern that communicating that the system is highly effective (i.e., overselling) creates a multitude of dangers. For instance, overselling can lead to the creation of a one-type-fits-all image of abductors who target children. This focuses the attention on more stereotypical abductors (e.g., strangers) and takes the focus off of people who are most likely to abduct children (e.g., family members). The message that AMBER Alerts are effective disregards the fact that most of the so-called successes occur in situations in which

the Alerts were never intended (i.e., family member abducts the child). Thus, people believe that these Alerts are effective at saving children from stranger abductions. This belief could lead people to focus on stereotypical abductors (i.e., strangers) and not focus on nonstereotypical abductors (e.g., family members).

Another danger of overselling AMBER Alerts is that there is little accountability for whether or not the policy is successful. Unquestioned promotion and acceptance makes it difficult to critically examine the policy to determine its effectiveness or to discuss ways to improve the policy. Overselling also discourages discourse about whether money could be spent in ways that would address more common child dangers or deaths (e.g., choking) as compared to rare events such as abductions.

Finally, overselling AMBER Alerts can lead to an increase in public panic. By overselling AMBER Alerts, people believe that child abductions are more common than they really are, possibly leading parents and children to be overly cautious (e.g., caution in making new relationships or allowing children to play outside). Although rescuing children is important, legal scholars have urged policy makers to be cautious in overselling AMBER Alerts because of such dangers.

AMBER Alert and Behavior: A Psychological Analysis

Psychologists have begun to study the AMBER Alert system. They focus, for instance, on the psychological reasons that AMBER Alerts might not work as intended as well as on the AMBER Alert's effect on psychological processes. A few studies address social cognitive processes related to AMBER Alerts. For example, child abductions can trigger hindsight bias (i.e., the *I knew it all along* effect, such as "I knew from the minute I read about the abduction that the child would be killed") under specific conditions: when the abductor is a stranger and when the abducted child is harmed. Although this study was conducted in a laboratory, it is likely that these effects increase support for real AMBER Alerts, as Alerts are designed to assist in cases of stranger abduction.

Similarly, in the event of a child abduction in which the child is not rescued, failure to issue an

AMBER Alert can result in more negative perceptions of the law enforcement agency in charge of issuing Alerts. According to one study, this occurs when the lack of an AMBER Alert was due to officer error. This phenomenon might occur due to community members engaging in counterfactual thinking (i.e., “if only” thinking, such as “if only the police had acted sooner, the child would’ve been rescued”).

Emotions (anticipated guilt, positive affect, and panic) and cognitive processing styles are linked to greater support for the AMBER Alert system. Specifically, negative emotions are associated with more positive attitudes toward AMBER Alerts, but positive emotions are not. Faith in intuition (i.e., the tendency to rely on one’s gut instincts in decision-making) is also associated with more positive attitudes, but need for cognition (i.e., the tendency to use logic in decision-making) is not directly related. Finally, the more people process information experientially (i.e., emotionally), the more positive attitudes they have toward AMBER Alerts.

Another line of psychology research has investigated whether attitudes toward AMBER Alerts can be altered through education. For instance, educating people about the low effectiveness of AMBER Alerts reduces support for AMBER Alerts but only if education occurs via high-quality messaging (e.g., messages that cite experts, statistics, and specific research). Similarly, education can reduce how much blame (measured as damage awards in a civil lawsuit) individuals assign to law enforcement in the event of a failure to rescue an abducted child.

Next, some research has focused on the effects of reading about abductions and AMBER Alerts. Reading about a child abduction causes heightened emotions, no matter the outcome of the abduction. Reading about an abduction labeled as an AMBER Alert leads participants to report that the message is more important and that they would make greater attempts to be involved (compared to reading about an abduction that was not labeled as an AMBER Alert). This suggests that the label of AMBER Alert prompts people to pay attention to the information, but another study found that reading about an AMBER Alert does not increase one’s ability to recognize faces.

Finally, limited research has found that certain groups of people (e.g., women, community members) are more likely to support the AMBER Alert system than their counterparts.

Researchers have suggested that some psychological phenomena might apply to AMBER Alerts, but these notions are yet untested. For instance, common errors in memory acquisition, retention, and retrieval are likely to make it difficult for the public to accurately identify a child and abductor. The bystander effect suggests that public participation is likely low because everyone believes that someone else who sees the Alert will help. Research on helping behavior suggest that social norms and pressure, individual characteristics, and perceptions of crime severity are related to helping behavior and willingness to report crimes to police in general. Researchers have also been concerned that AMBER Alerts could produce copycat crimes by media-seeking criminals, that Alerts could encourage the criminal to secure a different car than the one described in the Alert (in essence making the Alert counterproductive), and that the Alert system has little deterrent effect, as most abductors are not likely thinking rationally about the crime.

Future Directions in AMBER Alert Research

Criminologists, legal/policy analysts, and psychologists have studied a variety of aspects about the ALERT system, but there are many areas yet to be studied. First, research could reveal whether different Alert message formats (e.g., photographs, labels, media used) improve the public’s willingness and ability to respond to AMBER Alerts. Similarly, public service programs could attempt to encourage bystander intervention. Such measures would improve the public’s ability to assist with an abduction. Second, AMBER Alert outcomes could be explored. There has been some concern about Alert fatigue: Individuals might ignore or fail to remember AMBER Alerts more when these alerts are more common. Other outcomes worthy of studying include whether the issuance of Alerts prompt abductors to alter their behavior (e.g., to release the child or to kill the child as a means of destroying evidence of the abduction). Also, outcomes related to the public’s

behavior should be studied to determine whether exposure to information about abductions increases feelings of fear, exaggerated perceptions of abduction risk, being protective of one's own children, or fear of strangers. Finally, the psychological hypotheses discussed above could be the basis of future research more specifically concerning the AMBER Alert.

It is inherently difficult to study the real-world phenomena such as AMBER Alerts because it is impossible to predict when one will occur. Laboratory studies can only approximate the real-world responses. It is difficult to access perpetrators in order to study their motivations. Research is also difficult because there is no nation-wide database of Alerts, their circumstances, and their outcomes.

ANTISOCIAL PERSONALITY DISORDER IN INCARCERATED OFFENDERS, TREATMENT OF

Antisocial personality disorder (ASPD) is a recognized mental disorder that is substantially over-represented in offending populations. It is a complex and costly condition, associated with high rates of morbidity and mortality for the individual concerned and significant harm toward others. The American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* defines ASPD as a personality disorder that is characterized by deceitfulness, impulsivity, aggressiveness, disregard for the rights and safety of others, irresponsibility, and lack of remorse.

Epidemiological studies have found the prevalence of ASPD in men to be between 1% and 6% in general community samples, but the prevalence becomes increasingly higher in mental health services, the criminal justice system, and prison settings, with ASPD being represented in up to 80% of the prison population. ASPD is 3 times more common in men than women in the general population, although up to 30% of female prisoners are estimated to have ASPD. ASPD is associated with a significantly increased likelihood of committing violent behaviors, and the diagnosis is highly predictive of future violence, reconviction or reincarceration upon release, and severity of recidivism.

ASPD is also associated with considerable and complex comorbidity with other mental conditions, particularly alcohol and substance misuse and anxiety and depressive disorders. Individuals with ASPD are more likely to die at a young age due to reckless behavior and increased rates of suicide. The costs to society of people with ASPD who engage in criminal behavior include

emotional and physical injury to victims, damage to property, involvement with the criminal justice system, increased use of health services, lost employment opportunities, family disruption and relationship breakdown, childcare proceedings, gambling, and problems related to alcohol and substance misuse.

This entry begins with general findings regarding ASPD. It then describes the assessment methods and treatment approaches. The entry concludes with a discussion regarding issues faced by those treating patients with ASPD.

General Treatment Findings

Individuals with ASPD find it difficult to think of themselves as needing treatment as they associate this with weakness and vulnerability and therefore frequently reject any therapy offered. If treatment is mandated, as is often the case in custodial or probation settings, the offender may engage in treatment, but the apparent compliance may be motivated by the wish to be released rather than for any therapeutic benefit.

The evidence base for effective treatments for ASPD to date is limited in part due to the difficulties in engaging individuals with ASPD in treatment, let alone research studies. Most treatment trials have been conducted within the general offender population rather than samples consisting solely of offenders with ASPD. Moreover, research findings are hindered by differences between studies regarding treatment outcomes, diagnostic confusion regarding psychopathy and ASPD, and a focus on behavioral rather than personality change. This lack of an evidence base was highlighted in a 2010 review of all prospective randomized controlled trials (RCTs) for individuals with ASPD. This review identified 11 studies, all looking at a different psychological intervention, involving 471 individuals with ASPD, but only two studies focused solely on an ASPD sample. No study reported any change in antisocial behavior, leading the authors to conclude that there was insufficient trial evidence to justify any psychological intervention for adults with ASPD. The paucity of positive treatment findings contributes to the widespread belief among mental health professionals that the condition is untreatable.

Despite this, many treatment programs, mostly from a cognitive behavioral approach, have been

developed to reduce offending in prison and probation populations. Those found to have the largest effect size adhere to the Risk-Need-Responsivity model, which focuses on risk (targeting individuals at greatest risk of reoffending), criminogenic need (empirically based criminogenic risk factors such as criminal attitudes, substance abuse, and impulsivity), and responsivity (which types of interventions are most effective in addressing criminogenic needs). Risk of recidivism is reduced when the therapeutic relationship is characterized by caring, fairness, and trust. Interventions that focus on punishment, monitoring, control, and surveillance may increase risk of recidivism if not combined with rehabilitative efforts.

A structured approach to the management and treatment of offenders with ASPD considers the following clinical areas: careful assessment of the offender, including assessment of risk, psychopathy, and other personality characteristics that influence prognosis; specific treatment interventions; and monitoring the emotional responses of the professionals involved.

Assessment

Psychopathy

The most influential conceptualization of psychopathy within psychiatry was proposed by Hervey Cleckley in 1941 in his seminal book *The Mask of Sanity*. Cleckley vividly described the psychopath as a person who was incapable of feeling guilt, remorse, or shame; unable to form attachments to others; emotionally shallow, impulsive, egocentric, and grandiose; and unable to learn from experience and lacked insight. These characteristics have subsequently been empirically defined and measured by Robert Hare in the development of a reliable and valid risk assessment tool, the Psychopathy Check List-Revised.

Psychopathy is not, however, synonymous with a categorical diagnosis of ASPD. Empirical studies indicate that only one third of individuals in prison with ASPD have severe psychopathy, and this latter group has a significantly poorer treatment prognosis than do antisocial personality-disordered offenders with fewer psychopathic traits. The measurement of psychopathy and the use of other psychological tests help delineate subgroups of antisocial individuals who have lower

psychopathy scores and higher levels of anxiety, who may show a better response to treatment.

Violence

The most salient risk posed to others by offenders with ASPD is that of violence. This must be carefully assessed by validated risk assessment tools such as the Violence Risk Appraisal Guide, the Classification of Violence Risk, the Historical Clinical Risk Management-20 Version 3, and the Psychopathy Check List-Revised. Those who are severely psychopathic have 3–5 times the risk of violence than nonpsychopathic offenders. Ongoing risk management is an integral component of any intervention to reduce the risk of violence and antisocial behavior and typically includes attention to the setting in which treatment is delivered. Prison environments, particularly if they are overcrowded or based on power and control, may present significant challenges to staff in containing inmates' risk to themselves and others while facilitating rehabilitation. If the anxieties of staff are not addressed, this may lead to increasingly harsh and punitive regimes, which cause further discontent and resentment within the offenders, increasing their risk of harm to themselves and/or others.

Specific Treatment Approaches

Pharmacotherapy

The mainstay of treatment for ASPD is psychological therapy. Meta-analyses examining studies of pharmacological treatments of ASPD have found little evidence that these are effective in changing the primary traits of the condition or its behavioral manifestations. Medication is only recommended for the treatment of comorbid mental disorders such as depression, and close attention to adherence and misuse is advised.

Cognitive Behavioral Treatments

Most available psychological treatment programs for offenders with ASPD are based on cognitive behavioral and social learning principles and have been shown to have some effect in reducing risk in personality-disordered

offenders. These include relapse prevention programs such as Reasoning and Rehabilitation and Enhanced Thinking Skills, which integrate cognitive skills with social skills and problem-solving, anger and violence management programs, and sex offender treatment programs. Such interventions may be more effective when delivered within a group format rather than through individual therapy. Specific interventions for high-risk psychopathic individuals have been developed which adhere to the Risk-Need-Responsivity model and target dynamic factors directly linked to criminal and violent behaviors rather than underlying character traits.

Empirically based psychological therapies that include cognitive techniques and have been designed specifically for borderline personality disorder, such as dialectical behavioral therapy and schema-focused therapy, are increasingly used to treat personality-disordered offenders in forensic settings and have a growing evidence base for their effectiveness in this population.

Milieu Therapy

Therapeutic interventions may be more effective where there are concerted attempts to structure the environment in which the treatment is delivered. Milieu or residential approaches advocate that control of the environment surrounding the antisocial individual is the primary agent for change. There are two such approaches: token economies and therapeutic communities.

A token economy is a system of behavioral modification based on the principle of operant conditioning, whereby prosocial behaviors are positively reinforced by specific rewards or *tokens*—for example, allowing the offender more freedom and opportunities within the custodial setting. Such methods have been empirically shown to alter patient and staff behavior within institutions.

Residential therapeutic communities use a non-hierarchical group-based approach guided by four basic principles: democratization, permissiveness, communalism, and reality confrontation. Peer influence is seen as an important agent of change to encourage prosocial attitudes and skills. Although there has been little systematic research into the efficacy of therapeutic communities for

treating personality disorders, some evidence suggests that they are effective for antisocial personality-disordered offenders with comorbid substance misuse. Therapeutic communities remain popular in criminal justice settings, especially in the United Kingdom, and evidence from better designed RCTs suggest that this mode of treatment may be effective in offenders with ASPD.

Psychodynamic Treatments

There is little evidence that traditional psychoanalytic or psychodynamic psychotherapy is effective for offenders with ASPD, although this may reflect the paucity of well-designed RCTs for this treatment modality. There is emerging evidence that specific psychodynamic therapeutic modalities developed for personality disorders involving modifications of psychodynamic technique may be effective in ASPD. The most prominent of these is mentalization-based therapy that has a theoretical basis in attachment theory and combines cognitive and relational techniques and strategies. Trials of mentalization-based therapy have demonstrated that it is effective in treating patients with borderline personality disorder, and as of 2018, a major multisite RCT is being conducted for high-risk offenders with ASPD under the supervision of the National Probation Service in the United Kingdom.

Psychodynamic approaches may be helpful in understanding the unconscious determinants of antisocial behavior and how these may influence the offender's relationship to others and the offender's response to treatment. Moreover, psychoanalytic understanding may be usefully applied to the study of the dynamics of forensic institutions where the tasks of managing and treating dangerous and disturbed offenders may have a deleterious effect on staff and the institutional culture.

Family Therapy

Family therapy and other target interventions for children and families at risk may be effective for the prevention of ASPD. Children who show callous and unemotional personality traits and

those with conduct disorder are at higher risk of developing ASPD, particularly if they have experienced poor parental care or early environmental trauma and abuse. Parent training programs for high-risk parents, preschool nursery interventions, and home visits have been shown to be effective. Older children and adolescents with emerging ASPD may benefit from individual therapy augmented by family interventions such as functional family therapy, systemic family therapy, or multi-systemic therapy.

Countertransference, Supervision, and Reflective Practice

The stresses associated with working with antisocial offenders should not be minimized and may result in staff burnout, high levels of sick leave, substance misuse, and boundary violations in the relationships between staff and offenders. Exposure to dangerous, disturbing, and antisocial behaviors can eventually impact the professional's mental and emotional state.

Countertransference is a psychoanalytic term that refers to the somatic and emotional responses, some of which may be unconscious, that are evoked in the clinician or criminal justice professional by contact with the patient or offender. Common troubling countertransference reactions to personality-disordered offenders include feelings of moral outrage and disgust, therapeutic nihilism, devaluation and loss of professional identity, excessive fear or its opposite in the denial of real dangerousness, fascination, excitement and sexual attraction, and punitive and sadistic responses. Staff working in clinical or forensic settings often believe that it is unprofessional to harbor such feelings, and to reveal them indicates weakness of character and inability to effectively perform their job. However, if these emotional responses are not acknowledged and tended to, the person is more likely to act in unhelpful or inappropriate ways, for example, in overestimating the offender's risk so that the offender remains incarcerated or leading to conflict with other professionals.

It is therefore important for staff working with offenders with ASPD to have regular access to protected and confidential forums where their work and interactions with offenders can be

supervised and thought about. Although such reflective practice is often considered superfluous to the more goal-oriented tasks of managing risk and supervising offenders' activities, it is an essential part of the treatment of incarcerated offenders with ASPD in order to facilitate a containing environment in which both staff and offenders may work together safely and effectively.

ARSON

Arson is a legal term generally used to describe an unlawful act of deliberately or recklessly setting fire to property, be that to one's own property or that of another person. Although the general consensus is that an act of arson involves setting fire to property, the specific common law elements for an arson offense vary across jurisdictions. For example, some jurisdictions require a dwelling to have been set fire to for an arson offense to be brought to court. Other jurisdictions have different degrees of arson dependent on the severity of the harm caused (e.g., whether the building was

occupied or not, whether a person was harmed or killed as a result of the fire, or whether there was intent or recklessness as to the endangerment of life).

Arson presents a significant societal problem worldwide, accounting for a substantial number of fires attended by fire and rescue services and having a major impact on both society and the economy in terms of property damage and human life. For this reason, arson and deliberate fire setting constitute a serious societal problem, which requires attention from emergency services (e.g., police, fire and rescue services), the criminal justice system, policy makers, and practitioners to reduce its occurrence. This entry discusses the prevalence of arson, the characteristics of perpetrators, and explanations as to why people engage in this behavior.

Prevalence

Statistics from the Department of Communities and Local Government show that in the United Kingdom, in 2012–2013, there were 21,900 recorded deliberate fires resulting in 70 fire-related deaths and 1,300 nonfatal injuries. A similar picture is apparent in the United States and Australia. Statistics from the National Fire Protection Association show that between 2007 and 2011, U.S. fire departments reported receiving reports of approximately 282,600 deliberate fires per annum. These were responsible for 1,360 nonfatal casualties, 420 deaths, and US\$1.3 billion property damage. There are no officially recorded statistics for Australia; however, a report by the Australian Institute of Criminology estimated that in 2005, total costs associated with reported arsons were in the region of \$1.62 billion AUD. Further, the bushfires deliberately started in Victoria in 2009 are reported to have claimed over 200 lives.

Arson is considered a secretive crime, so detection rates are often low. This means that not all deliberately set fires will result in a conviction of arson, and therefore, conviction rates often severely underestimate the number of individuals in the criminal justice system who may have deliberately set a fire. Many factors can affect whether an individual is eventually charged and convicted of arson. Statistics are often confounded

by different sentencing practices. For example, a fire deliberately started to conceal evidence of another crime may result in a conviction of the primary offense (e.g., murder, theft of a vehicle) instead of arson. Further, not all deliberate fires are set to property (e.g., acts of self-harm using fire, setting fire to grassland) so may not result in any conviction at all.

Nomenclature

The terms *arsonist*, *pyromaniac*, and *firesetter* have historically been used interchangeably to describe individuals who deliberately set fires. However, these terms are conceptually different. As previously discussed, *arson* is a legal term which is generally defined as the unlawful damaging or destruction of property either intentionally or recklessly by fire. Thus, those who are generally convicted of arson are termed *arsonists*. Pyromania is a psychiatric disorder classified as an impulse control disorder not otherwise specified within the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders*, fifth edition (DSM-5). Those who meet the diagnostic criteria for pyromania and have received a diagnosis of this disorder may be termed *pyromaniacs*. Historically, the term *firesetter* has been used in the literature to describe juvenile offenders who have engaged in fire setting. More recently, there has been a move in the literature, and the term *firesetter* is now more commonly used to refer to all individuals who have engaged in deliberately setting a fire regardless of their legal (i.e., whether convicted or not convicted) or psychiatric status. Thus, the term *fire setting* encompasses the broad range of individuals who may present in clinical practice for having set deliberate fires.

Characteristics of Arsonists

Traditionally, deliberate fire setting has been assumed to be a crime that is primarily perpetrated by children and adolescents. Statistics indicate that just under half of all deliberate fires in the United Kingdom and United States are set by juveniles under the age of 18 years. Studies with community samples have reported that approximately 5–10% of children under the age

of 12 have engaged in fire-setting behavior. Although children and adolescents appear to account for a significant number of deliberately set fires, over half of all arson offenses are committed by adults. There has been no research to date that has examined how many individuals who deliberately set fires as children go on to do so as adults. However, a study in 2010 by Michael Vaughn and colleagues using the National Epidemiological Survey on Alcohol and Related Conditions in the United States examined the lifetime prevalence rates of deliberate fire setting in the general population. The results of the National Epidemiological Survey on Alcohol and Related Conditions survey indicated that 1% of the U.S. population self-reported having deliberately set at least one deliberate fire in their lifetime and that 38% of these individuals had a history of fire setting past the age of 15 years.

Research suggests that arson is predominantly a male-perpetrated crime. However, females with a history of deliberate fire setting appear to be overrepresented in psychiatric samples. In terms of basic demographics, research suggests that individuals who set deliberate fires are predominantly young, Caucasian, of low socio-economic status, and come from impoverished family backgrounds. In terms of educational attainment and employment, fire setters have been reported to have low levels of schooling and often have a history of unemployment or unskilled employment. Fire setters are also more likely to come from large families and have histories of neglect, sexual, and/or physical abuse compared to those who do not set fires. They appear to engage in a wide range of antisocial behaviors and are likely to have previous cautions and/or convictions for offenses other than fire setting.

Certain psychological characteristics have been highlighted in the literature as particularly pertinent among firesetters. Individuals who set fires are frequently reported to be characterized by loneliness, have poor social networks, and have difficulties in beginning and maintaining intimate relationships. In addition to poor interpersonal social functioning, firesetters are reported to lack social skills, often characterized by low levels of assertiveness, poor communication skills, and low levels of self-esteem. In comparison to

nonfire-setting offenders, firesetters have been found to self-report significantly higher levels of fire interest, identification with fire and cognitive experiences of anger (e.g., rumination and provocation), and significantly lower levels of fire safety awareness and personal self-esteem.

Mental health problems have long been associated with arson and fire-setting behavior. However, the majority of people who set fires are not reported to be mentally unwell. Pyromania is classified as a mental disorder under *DSM-5*. Individuals diagnosed with pyromania under *DSM-5* are broadly considered as those who repeatedly set intentional fires as a way to either relieve tension or arousal or experience instant gratification. The diagnostic criteria for pyromania are strict, and diagnosis is consequently rare. Research has reported prevalence rates of pyromania in samples of individuals who have set fires being reported at either 0% or around 3–10%. Under *DSM-5*, individuals who set fires for monetary gain, revenge, political protest, crime concealment, or to change living circumstances; those who set fires under the influence of substances, delusions, or hallucinations; and individuals with neurobiological or intellectual disabilities are not eligible for a diagnosis of pyromania. Thus, individuals with a diagnosis of pyromania are likely to represent a distinct group of firesetters. Although it is rare for individuals who have engaged in deliberate fire setting to hold a diagnosis of pyromania, several other psychiatric disorders have frequently been identified as being present in firesetters. Commonly reported disorders include depression, schizophrenia, conduct disorder (in juveniles), borderline and antisocial personality disorders, and substance use disorders, with borderline personality disorder and schizophrenia being the most commonly identified diagnoses.

Explanations

Unlike other types of offending, there is little literature or theories regarding why people commit acts of arson. A large proportion of the literature on arson has focused on identifying different motivations and deriving subtypes or typologies of arsonists based on these. Motives which have

commonly been identified in the literature as being associated with arson include revenge, excitement, fire interest, boredom, vandalism, cry for help, suicide/self-harm, attention seeking, anger, crime concealment, protest, psychosis or delusions, financial gain, heroic status, and protection. Revenge has been reported in the literature as the most common motives for deliberate fire setting. Some early writers hypothesized that deliberate fire setting was associated with repressed sexual urges and fetishism, whereby individuals set fires to watch them and become sexually aroused. However, researchers have not been able to find any empirical evidence to support this early hypothesis.

In addition to motive, both functional analysis and dynamic behavior theories have been used to try and explain why people might set fires. Both of these theories provide behavioral accounts of fire setting and consider the function of the act as a culmination of specific antecedents, behaviors, and consequences, which serve to reinforce fire setting. Professor Theresa A. Gannon and colleagues have developed the multi-trajectory theory of adult firesetting to specifically explain how individuals may come to set a fire. The multi-trajectory theory of adult firesetting hypothesizes that adult fire setting occurs as a result of an interaction between developmental factors (e.g., caregiver environment, social learning, the development of cognitive scripts, beliefs and attitudes about fire, and biological functioning), psychological vulnerabilities (e.g., inappropriate fire interest/scripts, offense supportive attitudes, self-/emotional regulation issues, and communication problems), proximal factors and triggers (e.g., life events, internal affect/cognition, cultural and biological factors), moderators (e.g., poor mental health and low self-esteem), and critical risk factors (e.g., psychological vulnerabilities which have become critical). The multi-trajectory theory of adult firesetting hypothesizes that key developmental factors in childhood create a set of psychological vulnerabilities, which are suggested to predispose individuals to fire setting. Proximal factors and triggers and moderators interact with, and reflect, psychological vulnerabilities, making them more chronic so that they become critical risk factors. Once these become critical risk

factors, individuals are considered to be at an increased risk of fire setting.

Recidivism and Treatment of Arson

There has been very little research into risk factors for deliberate fire setting, and reported rates of reoffending vary wildly. It has been estimated that approximately one in five untreated fire setters will go on to reoffend by setting another fire. Several factors have been identified as being potentially important for repeat fire setting. These include being younger, being single, having spent more time in correctional settings, holding an expressed interest in fire, having a history of childhood fire setting, holding greater levels of psychiatric disturbance, having a history of relationship problems, early onset of criminal convictions, and having a higher number of fire-setting charges.

Possibly due to the lack of research on recidivism and risk factors for fire setting, there has been little focus on providing specialist treatment programs for individuals who have set deliberate fires, with a distinct lack of any standardized treatment programs in the United States, United Kingdom, and Australasia. There appears to have been an assumption historically that firesetters' criminogenic needs can be addressed by general offending behavior programs (e.g., social skills, cognitive skills, anger management, problem-solving). However, these programs do not target any fire-related factors which research has shown distinguish fire setters from the rest of the offending population (e.g., fire interest, identification with fire, fire safety awareness). Two new standardized specialist treatment programs have been developed in the United Kingdom for individuals who set fires: The Firesetting Intervention Programme for Mentally Disordered Offenders and the Firesetting Intervention Programme for Prisoners. Evaluation of these programs shows that they are particularly effective in reducing firesetters' interest in fire and identification with fire and improving their fire safety awareness and regulation of anger.

ARYAN BROTHERHOOD

The Aryan Brotherhood (AB; aka Alice Baker, One-Two, or The Brand) is one of the most notorious prison gangs in the history of U.S. prisons. Although AB began in a single prison as a prison gang whose purpose was to provide protection to White inmates, its influence has spread throughout the U.S. state and federal prison system and even into communities. As members are released from prison, their lifelong commitment to the AB encourages engagement in criminal activities after release.

This entry reviews the history, organization, and criminal activities of the AB, one of the largest and most organized prison gangs in existence. It then discusses depictions of the AB in popular media and ends with a brief discussion of the AB in the 21st century.

History

In the 1950s, the Diamond Tooth gang was formed at California's San Quentin State Prison. Largely comprising Irish motorcycle gang members, it was named for the diamond chips embedded in members' teeth. One of the motivations for the formation of the gang was to provide protection for White inmates. In the early 1960s, as the gang grew in size and its influence spread, the gang changed its name to the Blue Birds. In the early 1960s, paralleling social movements in the communities, prison inmate populations began fractionalizing. African American inmates started the Black Guerrilla Family prison gang, and almost all African American inmates joined. The Black Guerrilla Family started competing for dominance with the Blue Birds. In response, the Blue Birds formed alliances with other White inmate groups, and in 1964, at San Quentin State Prison, these alliances led to the formation of the AB. The founders were two inmates, Barry "The Barron" Mills and Tyler Davis "The Hulk" Bingham.

As the AB gained power and influence, the gang formed additional chapters rapidly in other prisons in California. By the late 1960s, the AB had spread to numerous prisons in many other states. The Southern Poverty Law Center has reported that the AB has chapters in most federal and state prisons in the United States, with the largest AB membership in California and Texas. As its power and influence increased, the AB adopted a "blood in, blood out" oath (in 2016 Texas, "God forgives. Brothers don't"). Recruits are often required to commit a significant criminal act, such as murder, to fulfill the "blood in" oath. "Blood out" means the only way to quit the AB is by death. In some locations, new members have been required to read *Mein Kampf* written by Adolf Hitler. This was Hitler's political manifesto and blueprint for National Socialism (Nazism) as he created the Third Reich in Germany in the 1930s. Members

had to swear eternal allegiance to the gang, even after being paroled from prison, and in some cases adopt Asatru, a form of Odinism dating back to the Vikings and Norse gods.

Because of the lifetime commitment (under penalty of death if violated), the AB began to have an influence in criminal circles and gangs outside of prison. By the early 1990s, the AB had become involved in various forms of organized crime, including drug trafficking, prostitution, arms trafficking, extortion, dog fighting, and murder-for-hire. The AB also began working with other gangs and organized crime groups to further spread its influence and criminal enterprises. For example, in 1996, John Gotti, crime boss of the Gambino crime family (mafia) is alleged to have reached out to the AB to murder an inmate who attacked him while serving a prison term (Gotti's assailant was put in protective custody and never murdered). Membership in the AB is open to any White inmate, except those who are convicted of child molestation or who have served in law enforcement or as informants for law enforcement.

Organization and Criminal Activities

Some estimate that the AB has about 15,000 members in and out of prison, about 1% of the total prison population in the United States. The Federal Bureau of Investigation has reported that even though small in number, the AB is responsible for about 18% of all murders in federal prisons. Inside prison, the AB continues to engage in criminal activity, including drug smuggling, extortion, protection rackets, gambling, and murder.

Depending on location or state, the AB has different organizational structures, but all do have a structure. Most are paramilitary style and modeled after formal organizations, with presidents and vice presidents, generals, majors, captains, and lieutenants. Individual members are known as *soldiers*. In prisons, AB uses a council or committee to govern. In Texas, in addition to the paramilitary structure, the AB used The Wheel, a council of five generals in different regions of the state (all in prison) who govern AB activities throughout the state (both inside and outside of prisons).

In a major intelligence coup, in 1994, the Mississippi Bureau of Narcotics raided the residence of

AB member Bartow Usry. While an inmate at Parchman Farm, a Mississippi State Penitentiary, Usry had served as head of recruitment for the AB. Although Usry had moved shortly before the raid, he left behind two file folders containing information about the AB. In addition to detailing the inner workings of the AB, these folders contained a copy of the AB secret constitution and membership oath, an interview questionnaire for potential new members, a decoder for an AB prison code, and an organizational hierarchy chart. Information in the files listed characteristics that potential AB members should possess, including (a) belief in the racial purity of the White race, (b) genetically of European ancestry, (c) willingness to be supportive of the Brotherhood outside prison, (d) pact-bound, (e) obedient of all known Aryan laws, (f) noble and superior in nature, (g) honest in any and all Aryan business, among others.

Over the years, the AB has formed alliances and worked with other prison and community gangs and criminal organizations, including the American Mafia, Mexican Mafia, European Kindred, European organized crime groups, street gangs, motorcycle gangs, and drug trafficking organizations (cartels). The AB has historically been at odds with and has fought street gangs such as the Bloods, Crips, Black Guerrilla Family, Nuestra Familia, MS-13, Latin Kings, The Texas Syndicate, among others.

Throughout its history, the AB has been targeted by federal law enforcement, including the Federal Bureau of Investigation, the Bureau of Alcohol, Tobacco, and Firearms and Explosives, and the Drug Enforcement Administration, and state/local law enforcement in every state in which it has chapters. In 2002, leaders of the AB across the country were charged and tried under the Racketeer Influenced and Corrupt Organizations Act. Criminal charges included murder, conspiracy to commit murder, extortion, robbery, drug trafficking, and other lesser charges. In all, over 30 national and state leaders of the AB were convicted including the top four leaders of the AB: Barry "The Barron" Mills, leader of the AB for federal prisons; Tyler Davis "The Hulk" Bingham, top aide to Mills in the federal prison system; Edgar Hevle, federal inmate leader; and Christopher Overton Gibson, in charge of day-to-day operations. All were given life sentences to be served at the Administrative

Maximum Security Facility (Supermax) in Florence, CO. After being moved to Florence, authorities broke up a complex communication ring used by the leaders to remain in contact with members and to oversee criminal activity.

Many (if not all) AB members can be identified through body art. Most have multiple tattoos signifying membership, from a simple AB tattoo to more complex tattoos of swastikas, the number "666," HH (Heil Hitler), 88 (for the eighth letter of the alphabet), Sinn Fein-style falcon, double lightning bolts (Nazi SS), and other White supremacist-/racist-oriented tattoos. Not all states or chapters have the same identifying AB tattoo. For example, California AB members and chapters use the swastika and shamrock, whereas the Texas AB uses the swastika with sword and three-pointed shield.

In Texas especially, the AB have a large presence in the criminal underworld outside of prison. AB members have been involved in virtually all organized criminal activities, working with outlaw motorcycle gangs, drug trafficking organizations, organized crime, local street gangs, and even acting individually. The AB also engaged in making and supplying methamphetamine until it became cheaper to produce in Mexico. Now, the AB assists in the trafficking of the drug on the U.S. side of the border, as well as all other drugs that cross the border illegally. The AB has distribution networks established between states to facilitate the movement of drugs and weapons. Because of a brutal string of murders committed by AB members, in 2008, a federally led task force (Federal Bureau of Investigation, the Bureau of Alcohol, Tobacco, and Firearms and Explosives, Homeland Security, Texas Department of Public Safety, the Texas Department of Criminal Justice, and numerous city and county agencies) began a massive investigation of the AB. In November 2012, the task force arrested over 70 members of the AB, including almost all of the top leaders, some of whom were already incarcerated. By 2014, 73 had been convicted or pled guilty to numerous felony charges, receiving over 900 years in federal prisons combined without parole.

While the federally led task force impacted the AB in Texas, it did not stop AB criminal activities or reign. The AB is still a prominent force in Texas crime circles. It still has a major involvement in

drug and weapon trafficking, organized criminal activity, murder, and other felonious activity.

AB and Popular Media

The AB has been the subject of several contemporary documentaries, movies, and television shows. Documentaries that have explored the AB include *Marked* on the History Channel, *Gangland* on the History Channel, and *Aryan Brotherhood* on the National Geographic Channel. On film, the AB has been featured in *Supremacy*, *Honour*, *Snitch*, *Fire With Fire*, *Felon*, *The Death and Life of Bobby Z*, and *Lockdown*, among others. Television series that have built a storyline around the AB or have an AB element as part of another storyline have included *Law and Order*, *Prison Break*, *American Gang*, and *Breaking Bad*. Most notoriously, the AB had a significant presence in the series *Sons of Anarchy*. Several plot lines, while not mentioning the AB, were seemingly based on AB activities. For instance, in one episode, the motorcycle gang used a blowtorch to remove the gang tattoo of a disgraced member. In 2010, the AB attempted to kill Albert Parker by using a blowtorch on the AB tattoo on his rib cage.

The AB in the 21st Century

Today, the AB remains a White supremacist gang. For many White prison inmates, it is a gang to join for protection and personal safety. Despite efforts of the federal government and law enforcement, the AB continues to be a major force in the prison gang culture and prison life. Many inmates find safety and security in becoming an AB, so upon release from prison, they remain an AB. Outside the walls, the AB continues to engage in significant criminal activity and

be a force in the criminal underbelly of communities. Although White supremacy is the driving force of the gang, racial ideology has been supplanted by organized crime activity, which provides money to members, as it is more profitable for the AB to engage in criminal activity than racial activity.

B

BASIC MENTAL HEALTH SERVICES VERSUS REHABILITATION

Traditionally, the goals of correctional mental health treatment have been basic, not rehabilitative. Basic mental health service goals for inmates have been primarily stabilization: to enable the patient/inmate to stay out of trouble while incarcerated, and once released, for the patient/inmate to be less likely to recidivate. Mental health rehabilitative efforts provide more than just basic mental health services. Rehabilitative efforts focus on tailor-fitting treatment to offenders so the offenders understand what precedes their thoughts and their behavioral *triggers*. In addition, rehabilitative efforts focus on lifestyle change and prosocial behavior.

This entry discusses the history of why mentally ill people are increasingly treated in correctional settings. This is followed by a discussion of current issues in forensic mental health and the Risk-Need-Responsivity model. Barriers to treatment are discussed, along with treatment modalities (cognitive behavioral therapy [CBT] and reasoning and rehabilitation [R & R] therapy). Finally, a culminating discussion is provided concerning basic mental health services versus rehabilitation.

History

People with mental health problems are incarcerated for a variety of reasons: (a) they are convicted of a

crime; (b) the mental health system currently does not have adequate hospital beds and community mental health supports; and (c) current laws make it difficult for professionals to treat people with mental illnesses who are unwilling to be treated.

The peak year for inpatient psychiatric hospitalization in the United States was 1955 when 640,000 people were held in public and private hospitals. Since 1955, improvements in medicine, advocacy for more humane treatment, and fiscal constraints resulted in most psychiatric beds being closed. By 1980, 90% of the hospital beds in the United States had closed, and the average length of hospitalization had decreased from 6 months to less than 1 month. In 2018, the average length of stay was 10 days. As hospital beds emptied from 1955 to 1980, community mental health centers were intended to provide supports to people with mental illnesses living in the community. In other words, those people who would have received mental health treatment in hospitals in the past would now receive those services in the community. This plan, however, has not been realized. Many people with mental illnesses have fallen through cracks in the system and have ended up homeless, in nursing homes, or even incarcerated.

In 2016, sizeable portions of the U.S. jail and prison populations needed mental health treatment. Among prisoners, 37% reported to corrections officials that he or she had been told by a mental health professional that he or she had a mental illness. Among those in jails, the percentage was 44%. Research reveals that prisoners or detainees with mental illness are more likely than

those without to have behavioral problems while incarcerated. If inmates with mental illness do not have their problems addressed while incarcerated, they are more likely to recidivate.

Current Issues in Forensic Mental Health Services

While stabilization focuses on basic mental health services (e.g., better behavior in prison and a decrease in recidivism), rehabilitation attempts to create a change in lifestyle and promotes prosocial behavior. The goal of rehabilitation is not merely symptom reduction but also a way to avoid antecedents and triggers. Simply put, the goal of rehabilitation is to provide the person with mental health problems a way of living a better life—one that allows the individual to thrive, not simply to survive. The World Health Organization defines health as not merely the absence of disease (and accompanying symptoms) but also as the ability to thrive.

Some people are not happy with the idea that criminals should receive rehabilitation, which is above and beyond basic mental health services. Critics of rehabilitation claim that criminals do not deserve more than basic care, that criminals should not receive extensive and expensive treatment, and that rehabilitative treatment is not effective. However, research reveals that rehabilitative treatment works and is financially sound. For many researchers and practitioners, the question is not whether rehabilitative mental health treatment works but it is what specific treatment works for which person and under what circumstances.

The Risk-Need-Responsivity Model

This Risk-Need-Responsivity model has shown promise since 1990. This model first focuses on risk assessment of the specific inmate. While it is difficult to predict exactly what one inmate will do in the future, individuals can be classified by risk of reoffending, such as high risk or low risk. Historically, risk assessment was a professional opinion based on those who worked with offenders. Physicians, psychologists, and correctional officers would provide inmate risk assessments based on their experience with inmates in general

and their impression of a specific inmate. This method was later replaced by the use of actuarial assessments of inmates based on evidence-based information. In other words, collecting information about an inmate's risk factors (e.g., substance abuse, violent behavior) predicted future behavior better than a professional's opinion.

This newer method of assessment is similar to how insurance companies set policy rates. No one knows exactly who will get in a car accident, when the accident will happen, how much damage will be done, and what costs will be incurred. If an insurance company sets its customers' premiums (how much each insured person must pay) too low, it will not have enough money to pay off claims and will go out of business. Conversely, if an insurance company sets the premiums too high, the company will not be competitive and go out of business. To stay in business, then, insurance companies must find a way to differentiate high-risk customers from low-risk ones. The insurance company, then, can charge high-risk customers more and low-risk customers less.

The justice system, using evidence-based risk factor analysis, is able to place inmates into higher and lower risk categories. The rehabilitative services must target those who are in the highest risk of reoffending because that is where the rehabilitative services will have the biggest impact. Then, the specific need must be targeted so it can be matched with the correct response. For instance, a person may have problems maintaining his or her composure and become too angry too quickly. To reduce this person's risk of recidivism, anger management can be provided. If the inmate's problem is interacting with people who are procriminal, then the person needs to develop relationships with people who are prosocial in their orientation. By doing this, correctional rehabilitative efforts do the most good for the most people. If rehabilitative efforts are not tailored to individuals, then the wrong kind of efforts will be spent on those who do not need them. The rehabilitative efforts, therefore, will not do the most good for the greatest number of people.

Barriers to Treatment

The correctional system can use risk analysis to determine who should be treated. Oftentimes,

though, those with the greatest need of treatment are unwilling to participate. Younger inmates are less likely than others to want to receive treatment. Other treatment barriers exist that must be dealt with in order for treatment to start and be efficacious. Inmates may not want to participate for several reasons:

1. The inmate may believe that entering treatment in a correctional setting will make him or her appear weak. Prison inmates live in a world that is full of very real physical and psychological dangers. Any inmate showing weakness risks inviting abuse from other inmates.
2. Some inmates, as well as people living in the community, may not understand how to access treatment. Inmates may not know with whom to talk, what forms to fill out, or other details about how to get into treatment.
3. Inmates may believe that they must be self-reliant. Such inmates may believe that seeking treatment cannot help them—that the best course of action is relying solely on themselves.
4. Inmates may also have concerns about mental health-care providers and the providers' ability to treat them adequately.

Corrections officials may have the perfect treatment to provide to the highest risk offenders to reduce recidivism the greatest amount. But, if the inmate in need of treatment is unwilling to participate with mental health-care providers, then treatment will not occur, and the mental health rehabilitative efforts will not be optimal. Correctional officials, then, must actively attempt to reduce barriers to treatment in a correctional setting. To do this, inmates need to be provided general education about rehabilitative treatment along with procedural instructions on how to access treatment; stigma must be reduced for correctional mental health treatment; and confidentiality must be provided.

Treatment Modalities

One of the most successful ways to treat inmates with mental illness in a correctional setting is to use CBT in general and R & R specifically.

Research shows that CBT works with a wide variety of offenders. The R & R approach attempts to address inmates' problematic thinking styles and poor reasoning skills. For instance, a man who has been assaulted may come to believe that his only course of action is to find the person who assaulted him and to kill his attacker. CBT would help the man learn that killing someone who hit him is *too much* and that there are other options to deal with this issue such as contacting the police. R & R provides patients with 8–9 months of treatment with a couple of hours of group treatment (6–12 participants) each week. The R & R treatment program uses a variety of techniques to help patients change their rigid way of thinking and subsequently develop a new set of skills to solve problems. The goal is to solve problems in a way that is prosocial and not criminal.

Discussion

Basic mental health services in correctional settings focus primarily on stabilization: helping the inmate to behave while he or she is incarcerated and to not recidivate after he or she is released. Rehabilitative efforts seek to improve the lifestyle of inmates while teaching them about what triggers them to react in a way that is antisocial and possibly even criminal. Corrections officials try to do the most good for the most people by first assessing an inmate's risk factors through evidence-based, actuarial analysis. Correctional mental health treatment should focus on those with the highest risk of recidivism, but the specific treatment should be tailored to the inmate by responding to his or her specific needs. For mental health rehabilitative efforts to work, barriers to treatment must be addressed. Rehabilitative efforts are considered superior to basic corrections mental health services because rehabilitative efforts are more likely than basic mental health services to reduce recidivism in a manner that is not more expensive.

BEHAVIOR MODIFICATION

Behavior modification is the systematic application of basic principles of learning, operant conditioning, and classical (Pavlovian) conditioning to change human behavior. Basic principles from operant conditioning used in behavior modification include reinforcement, stimulus control procedures, functional analysis of problem behavior, and punishment techniques to a lesser extent. Used as a *management technique*, behavioral principles are utilized by staff with patients, students, employees, or inmates. In *behavior therapy*, both parties, one of whom is usually someone with health-care credentials, freely consent to participate toward mutually acceptable goals—but using the same principles.

Using behavior modification principles under the title of an applied behavior analysis (ABA) requires licensure or certification in most states and is growing worldwide. ABA is the only scientifically established effective treatment for autism spectrum disorder, and as of 2017, many countries and 44 U.S. states mandate insurance coverage for ABA treatment for autism spectrum disorder.

Behavior modification is often misleadingly presented in textbooks and media as a simplistic approach that relies on electrical shock and other aversive techniques derived from classical conditioning such as associating a sickness-inducing drug with an undesired behavior. When behavior modification first was being developed, there was limited use of such techniques, and in some very rare cases, aversive conditioning might still be used. But from its beginnings in the early to mid-20th century, behavior modification

programs almost invariably were centered on the systematic use of positive reinforcement to increase appropriate functional behaviors of individuals be they patients, clients, employees, juveniles, prisoners, or parolees. This entry examines the role of behavior modification in criminology, including reducing criminal behaviors, improving the lives of the incarcerated and the effectiveness of corrections staff, and reducing recidivism.

Modern Behavior Modification and Its Application

Effective behavior modification in its modern form, especially in institutions or corrections, involves at least three elements. First, *clear contingencies of reinforcement* are consistently applied to establish and maintain specifically defined appropriate behaviors. Second, *token economies* are in effect. In token economies, when specifically defined appropriate behaviors (e.g., academic, social, vocational) are performed to standard, tokens (chips or points) are earned that may later be exchanged for goods, activities, or other privileges. For example, completing academic work or cleaning common areas may earn points that can be exchanged for extended television time or extra canteen money. In some systems, loss of tokens, *response cost*, occurs contingent on the occurrence of specific previously defined unacceptable behaviors (e.g., aggression, rule breaking). Third, *contingency contracting* or *behavioral contracting* is used. A contingency contract is a written agreement between the patient, inmate, or client and the authority (e.g., therapist, teacher, corrections official) that states a contingency between explicitly defined behavior (what, when, and where) and reinforcement for the behavior—a written *if-then* statement. For example, “If my urine sample comes back clean, then my home visit may be extended by two hours.”

By changing the behavioral trajectories of those who otherwise develop patterns of criminal behavior, making prison more rehabilitative, and by reducing rates of recidivism, ABA and behavior modification more generally has been shown to be an effective approach in correctional settings. However, despite its effectiveness, behavior modification has not been widely adopted in

criminology for various reasons including staff resistance, the political cost of appearing *soft on crime*, and misunderstandings of behavior approaches to crime and crime prevention.

Modern Behavior Modification and Criminal Behavior

The theory and practice of modern behavior modification is built on the *law of effect*, first elucidated by Edward Thorndike over a century ago. The law holds that *given several responses to the same or similar situations, responses closely followed by satisfaction are more likely to be repeated and those responses followed by dissatisfaction are less likely to be repeated*. The law of effect was refined by the late Burrhus Frederic Skinner and his intellectual descendants into the principles of reinforcement (positive and negative), punishment, and stimulus control. According to the law of effect, whether criminal or law-abiding behavior occurs in certain situations depends on whether these behaviors are closely followed by reinforcement or punishment in those situations.

For most people in most situations, the law of effect selects a pattern of law-abiding behavior because in most situations, lawful behaviors are reinforced and criminal or deviant behaviors are more likely to be punished. But even for law-abiding citizens, in some situations, some law-breaking behavior is selected. For example, when driving a car, speeding is often selected because speeding is more often closely followed by reinforcement (e.g., a faster arrival time) and less often by punishment (e.g., a speeding ticket or accident).

The phrase *the dysfunctional is functional* summarizes the behavioral perspective on what causes and maintains dysfunctional or illegal behavior. If a behavior repeats, it *must* be being reinforced in some way or it would not recur; it must be functional at least in the immediate, if not in the long run. Illegal drug use removes aversive withdrawal symptoms and quickly gets the user *high*. Drug use rewards the user. Rape may result in feelings of power and thus is reinforcing for the rapist. Aggression can immediately terminate an aversive social situation or produce compliance in others. Aggression is functional for the aggressor.

Selection of, and Prevention of, Criminal Behavior in the Young

For some children, beginning early in life coercive, defiant, and aggressive behaviors are selected by the reinforcement contingencies prevalent in the home environment. As these children grow and spend more time in school and in peer-dominated environments, the contingencies continue to select and reinforce aggression, deviant, and criminal behavior.

Removal of demands by mothers unintentionally reinforces the aggressive behavior of young boys who later become deviant. When these children enter school, defiance and aggression continue to be negatively reinforced as parents and teachers terminate demands and demand less in response to aggression. Peers increasingly reinforce antisocial behaviors as well as tobacco, alcohol, and other drug use (e.g., through praise and acceptance). By their teen years, these now antisocial youths have had their dysfunctional, criminal behaviors selected because such behavior, relative to normative behavior, has most often been positively reinforced. *Dysfunctional* criminal behavior is functional in this milieu.

To counter reinforcement contingencies that may select coercive deviant behaviors, parent behavioral training utilizes behavior modification, teaching the parents of children at risk for conduct problems to monitor and reinforce appropriate behaviors. Parents are first taught to monitor their children's whereabouts and attend to their appropriate behaviors. Often to the parents' surprise, children's appropriate behaviors frequently increase just in response to being attended to in a nonpunitive manner. Next, parents are taught simple reinforcement procedures for appropriate behaviors, such as verbal praise contingent on compliance or perhaps a simple reward or token system where tokens or points are earned that are later exchanged for a small treat, toy, or activity. Finally, nonphysical punishment techniques are taught including ignoring, time-out from positive reinforcement, and response cost (fines). Prior to being trained in these basic behavior modification procedures, these parents typically used physical punishment (beatings) or loud reprimands. Physical punishment has been shown to increase aggression in these already aggressive children.

At-risk children whose parents received parent behavioral training have fewer law violations, less aggression, and less institutional confinement later in life compared to at-risk children whose parents did not receive behavioral training.

Older at-risk children may encounter behavior modification in residential treatment programs such as the teaching-family model, in Boys Town programs, or other organizations using positive behavioral supports. These programs provide some sort of token, point, or level system of positive reinforcement. Social skills are broken into small manageable components, practiced and reinforced. Children receive at least 4 times as much praise as correction. Appropriate behavior and academics are taught equally. While these programs are underutilized, their results are dramatic. When implemented in inner city schools, academic scores have risen and incidents of serious misconduct have decreased by as much as 80%.

Behavior Modification in Prison

In prison, coercive interpersonal manipulation is common by both prisoners and correctional staff. At best, a harsh punitive approach may suppress criminal behavior but will not facilitate lawful behavior. Instead the prevailing reinforcement contingencies in most prisons *teach* criminals to be better criminals. But when behavior modification programs have been used in prisons, largely during the late 20th century, they have been effective in reducing aggression and other antisocial behavior by inmates.

In the United States, prisons have become default psychiatric institutions. Behavior modification programs, specifically token economies, can be a cost-effective treatment within a single state institution for both individuals with a severe behavior disorder and individuals with a persistent psychiatric disorder. State and federal prisons and psychiatric institutions can all be noisy, chaotic confusing places. Inmates and patients usually come from dysfunctional home environments that reinforced and thus selected their criminal and antisocial behavior in the first place. But when introduced into institutions, behavior modification programs have decreased chaos, confusion, and aggression.

Human social interactions are often complex and the contingencies of reinforcement are subtle. Token economies simplify interactions and clarify contingencies. This allows inmates to make informed choices about their behavior and experience positive reinforcement for prosocial behaviors or experience response cost (fines) in a calm, controlled environment. Token economies have improved the behaviors and environment of institutionalized persons and have reduced recidivism.

Behavior Modification and Recidivism

Behavior modification programs that utilize contingency contracting and token economies have repeatedly been shown to be effective in establishing and increasing offenders' appropriate behaviors and reducing recidivism. However, if the contingencies of reinforcement for lawful behavior are not maintained, desired behaviors decrease eventually, perhaps to extinction, and old patterns of criminal behavior may be reestablished, selected by the dysfunctional contingencies in the offender's home environment. But when a component is added that uses behavioral learning techniques to change general adaptive behaviors, a new repertoire of social skills gives one the ability to obtain reinforcement in acceptable ways rather than in illegal ways. For example, traffic, employment, or interpersonal difficulty responded to in a verbally firm but respectable manner is more likely to be reinforced with assistance, while a disrespectful confrontational interaction is more likely to escalate and result in aggression, arrest, or worse. When social skills training and aggression replacement programs are included as part of correctional behavior modification treatment programs, recidivism is reduced even further. In sum, behavior modification can reduce delinquent, antisocial, and criminal behaviors in the young; improve the lives of the incarcerated and the effectiveness of those whose job is to rehabilitate criminals; and reduce recidivism among those who have committed crime.

BEHAVIORAL GENETICS AND OTHER BIOLOGICAL INFLUENCES ON CRIMINAL BEHAVIOR

Behavioral genetics explains the genetic contributions to both normal behavior and behavioral aberrations. Two general strategies are utilized by researchers. The *top-down* approach, behavioral genomics, begins with atypical behaviors and identifies genetic aberrations (e.g., less common alleles, including single nucleotide polymorphisms) in the atypical group. Single nucleotide polymorphisms are variations in nucleotide sequences between individuals from single base-pair alterations, missing base pairs (deletions), additional base pairs (insertions), or number of copies of a gene. The *bottom-up* strategy involves tracing an atypically functioning gene product (e.g., protein) to its DNA and the function of the gene product through its influence on neuronal function in information processing and its expression in behavior. Ideally, the two are complementary, providing complementary understanding of behaviors of interest.

These strategies would be straightforward if different phenotypic outcomes were pleiotropic, whereby different phenotypic outcomes are governed by single genes or gene products

(proteins). Complicating reality are (a) *oligogenic traits* that are determined by relatively few genes and (b) *polygenic traits*, whereby phenotypic outcomes are determined by many traits, confounding of diverse symptoms traceable to different sets of genes within single diagnostic entities. These complexities have led some researchers to focus on *endophenotypes*, which are more specific, measurable biological or behavioral markers found in higher frequencies in individuals with particular disorders than in the general population. Because of their greater uniformity than diagnostic entities, they are expected to map more directly to specific genes. Endophenotypes can also be present prior to full manifestation of a disorder or disease.

Heritability of Criminal Behavior

Classical designs in human behavioral genetic studies utilize differences in genetic similarities afforded by identical twins (sharing virtually 100% of their genomes), fraternal twins or siblings (sharing approximately 50% of their genomes), and adopted siblings sharing presumably similar early family environments but minimal familial genetic similarity. *Heritability* refers to how much variability in the trait under study can be attributed to genetic as opposed to environmental influences. Environmental influence can be further subdivided into shared (early family) and unshared (post-early family) environmental influences.

A number of findings about genetic and environmental influences on crime appear consistently across the literature with a few exceptions. Not surprisingly, the consensus from twin studies comparing monozygotic (identical) and dizygotic (fraternal) twins demonstrates that monozygotic twins are more concordant for criminality than dizygotic twins by a factor of 2. This underlines a significant role for nongenetic contributors to criminality.

One surprising finding in the earlier literature was that the genetic link to crime applied to non-violent crime but was not evident for violent crime. More recent studies, perhaps owing to more refined methodologies, have reported genetic associations with aggression and violent crime as well as genetic distinctions between adolescent-limited

and life-course-persistent criminal groups. Further attesting to genetic influence on criminality are the greater concordances between children's criminality with their biological rather than with their adoptive parents. It has been estimated that about 50% of heritability of criminal behavior is attributable to genetics, with the other 50% attributable to the environment.

Psychobiology and Criminal Behavior

Clearly, a single gene or set of genes does not determine that an individual will commit crimes in general or any specific crime in particular. In general, genes, in conjunction with early environmental influences, can impact perceptions, cognitions, emotions, and motivational states in response to immediate environments that bias decision-making in specific ways relative to what a particular society deems illegal. Any gene generically linked to crime can affect diverse brain pathways (pleiotropy) that may have a variety of functions. Conversely, functions of individual brain pathways can be affected by numerous genes (polygenicity). To link genes and downstream biology to the general notion of *crime* may obscure the extent of genetic or biological influence because those factors may be associated with only specific aspects of criminal behavior, lowering correlation or concordance levels when applied across undifferentiated *crime*.

Accordingly, it is necessary to specify different types of crime in terms amenable to *biological dissection*. The criminological literature provides different ways of doing this, such as severity of crime (e.g., murderers vs. nonlethal assaults vs. property crimes), persistence (adolescent-limited vs. life-course-persistent criminals), and sex offenders versus nonsex offenders. From the biological side, criminals have been studied with respect to differences in brain structure, inferred by neuropsychological studies and directly by structural neuroimaging via magnetic resonance imaging, brain activation states (using electroencephalogram [EEG] and functional magnetic resonance imaging), or peripheral electrophysiological measures (e.g., resting heart rate), reflecting psychophysiological systems hypothesized to predispose individuals to criminality. This impressive corpus of research has not yet entered mainstream forensic or correctional practice.

In general, crime, like any other behavior, results from a confluence of motivational, cognitive, and emotional information, typically in response to an immediate environment but biased by earlier exposure to the consequences of such settings. Typical motivations for crime initiation include (a) opportunities for immediate or future tangible gains (*instrumental/predatory aggression*), (b) frustration/anger (*irritable aggression*), or (c) fear (*defensive aggression*). One characteristic of instrumental aggression is that the severity of violence, once initiated, is largely limited by goal attainment. Consequently, a mugger will threaten but escape the situation with the wallet or purse. Once attained, the aggression ceases. (Sex offending falls within this classification.)

In contrast, once an irritable aggressive act is initiated, it continues regardless of the extent of injury to the victim, generally out of proportion to the initiating cause. Irritable aggressors recidivate consistently despite the expressions of genuine remorse, as is often observed with spousal abusers. Defensive aggression commonly occurs with mentally disordered offenders who have persecutory delusions wherein they misperceive being attacked. Psychopaths and narcissistic types can feel attacked by threats to their positions in social hierarchies and act violently to remove the threats. This classification system refers to the primary factors that motivate and initiate crime. It is recognized that once a crime is in progress, immediate situational factors can occur that introduce an alternate motivational impetus to modify the dynamics of the crime.

Providing a coherent, reductionistic, biologically referenced framework is critical for identification of neuropsychological, neuroanatomical, pharmacological, and genetic substrates of any type of crime. For instance, looking for the neurobiological substrate of irritable violence in instrumental offenders necessarily will result in false-negative results, obscuring relationships between biological causes and observed criminality. It is possible that effect sizes in some studies have been suppressed by including different aggression types in undifferentiated analyses. Consequently, it is important to classify selected findings by aggression type at (successive) levels of biological organization.

Decision-making also involves regulation that occurs through inhibitory mechanisms referred to at the psychological levels by terms such as *self-regulation*, *inhibition*, *long-term planning*, and *good judgment*: aspects of higher-order processes referred to as *executive functions*. A salient aspect of such self-regulation is the ability to delay gratification to a more appropriate time, place, and often source of gratification. Although executive functions are not restricted to the frontal lobes of the brain, frontal lobe neurons possess the ability to continue firing at steady rates for much longer periods than other neurons, affording them a particular advantage to maintain inhibitory control over extended periods.

Saliently, the frontal lobes are further subdivided into areas that regulate cognition (dorsolateral prefrontal cortex), emotion (orbital prefrontal cortex), and motivational states (ventromedial prefrontal cortex). Pathways from the dorsolateral prefrontal cortex project to other cortical areas to organize cognition. Orbital prefrontal cortex projections regulate centers such as the amygdala, where intensity translates into emotions such as fear and anger are initially processed. Ventromedial prefrontal cortex neurons modulate motivational centers. Pharmacologically, approach behaviors are facilitated by the neurotransmitter dopamine (DA) that focuses attention on a potential rewarding target, processes pleasure states associated with rewarding objects and activities in the ventral tegmental area and nucleus accumbens, and filters out competing information. Endogenous opioids heighten pleasure experiences synergistically with DA. Testosterone (T) helps energize approach behaviors but is also activated in angry states. Glutamate at the *N*-methyl-D-aspartate receptor is involved in learning what settings, situations, and responses lead to rewarding outcomes. Together, these transmitters and hormones may be considered the pharmacological *approach system*. Easily triggered and rapidly reactive approach systems can lead to impulsive approaches to immediately gratifying behaviors. Extremely sluggish and slowly responding reward/approach systems may lead to missed opportunities in life, chronic feelings of emptiness, and boredom that in some individuals trigger sensation-seeking behaviors (i.e., drugs, thrill-seeking) to counter what has been called *reward deficiency syndrome*.

Countering this *approach complex* is a set of neurotransmitters and hormones that serve as *brakes* on the approach system. First, serotonin (5-HT) projects to the ventral tegmental area and consequently inhibits DA. 5-HT also lowers T levels. This interruption of reward processing allows for cognitive consideration of the long-term consequences of the available immediate gratification and a more sound behavioral decision. This is consistent with the use of serotonin specific reuptake inhibitors to counter impulsivity. Not all people who avoid unsound decision-making think their way out of the situation. Others utilize the *emergency brake*, experiencing anxiety or fear to avoid what *feels* like a risky situation or activity. This is initially processed by norepinephrine, and if the anxiety or fear persists, the stress response is activated and cortisol, a glucocorticoid hormone, is released by the adrenal gland. Cortisol has an inhibitory effect on DA, disrupting attentional focus on reward. Excessive cortisol has the immediate effect of disrupting optimal connectivity between neurons, leading to momentary disorganization. Automatic or dominant responses can occur during such stressed states.

Psychobiology of Decision-Making and Aggression Types

The preceding neurobiological framework for organizing approach and avoidance systems can be related to aggression types. Predatory/instrumental aggression reflects activation of the ventral tegmental area–nucleus accumbens tract using DA. This can be intensified by endogenous opioids and further energized by T. Consequently, individuals could have excessive reward focus by possessing atypical genetic or epigenetic characteristics facilitating any or all of these elements.

Anger, as noted earlier, involves T and can be countered by either 5-HT or anxiety/fear involving norepinephrine or cortisol. 5-HT's importance in curbing irritable aggression is supported by the approval of five serotonin specific reuptake inhibitors (citalopram, escitalopram, fluoxetine, paroxetine, and sertraline) for anger management by the FDA. Consequently, allelic variability in T, 5-HT, NE, or cortisol could impact an individual's propensity to aggress in response to frustrating

experiences. It has also been reported that high (baseline) T to (stress-induced) cortisol ratios occur in psychopaths.

The central nucleus of the amygdala has direct correlations to the hypothalamus and brainstem—areas directly related to fear and anxiety. Fear conditioning, whereby a neutral stimulus acquires aversive properties, occurs within the right hemisphere. Norepinephrine and corticotropin-releasing factor are implicated in processing fear. Repeated stress alters amygdala responsiveness to additional stressors in the presence of circulating glucocorticoids such as cortisol. Consequently, genetic variability in these hormone and transmitter systems might impact susceptibility to defensive aggression.

Although not extensively studied, available information supports the notion that it is not the absolute, isolated level of a particular hormone or transmitter that influences approach or avoidance decision-making but their ratios (i.e., between testosterone and cortisol). Moving upstream, genetic and possibly epigenetic alleles could underlie the observed phenotypic differences.

Translating Neurobiological, Genetic, and Epigenetic Knowledge Into Criminological Research and Practice

Although the likelihood of implementing comprehensive assessments of criminals and mentally disordered offenders at all of the levels discussed in this entry is presently unfeasible for practical (i.e., resource-based) reasons, psychologists who possess the requisite background could utilize existing psychometric and electrophysiological methods to initially validate and then implement the implications of this recent knowledge. Specifically, psychometric instruments exist that can reliably measure strengths of different motivational and emotional systems covered herein. Similarly, numerous neuropsychological tools exist that can reliably evaluate executive function (e.g., inhibitory regulation), along with the strengths of distinct emotional and motivational systems. Examining individuals' criminal histories in light of the relative prevalence of predatory, irritable and defensive aggression events in a criminal record can be used as the outcome variable in modeling expected aggression and criminal patterns. Concurrent

electrophysiological monitoring of EEG and galvanic skin response could enhance interpretation of performance failures on neuropsychological testing. This is an ambitious agenda that carries a potentially significant reward in enhanced understanding of how individuals commit crimes and an appreciation of why they commit the crimes they do. This would lead to more helpful interventions than incapacitation by lengthier incarcerations.

BEHAVIORAL THEORY OF CRIME

Behavioral theory distilled to its core asserts that an individual's behaviors are functional choices. Traditionally, the function of behavior has been broken down into five basic categories of goals: tangible reinforcement, attention, avoidance, escape, and sensory stimulation. Goals are achieved using an array of behaviors across

different settings, all considered adaptive by an individual at that time. Behavioral choices are influenced by individual and intrapersonal variables, factored into an economic equation including values and preferences of the person and his or her cultural group, perceived costs of the act, probability of success, and likely consequences.

Certain behavioral choices, such as substance use, gang participation, or a shopping spree, may be thought preferable at the time but reap problematic long-term consequences for the individual. Criminal behaviors may be effective for the individual in getting what he or she wants on a short-term basis, despite the mainstream culture's decree that this behavior is maladaptive, expensive, inconvenient, dangerous, or offensive. This entry begins by reviewing the functions of behavior. It then examines the application of behavior principles to crime and concludes with a discussion of the challenges associated with applying behavioral theory to crime.

Understanding Functions of Behavior

The antecedent–behavior–consequence chain is a behavioral explanation for how an individual's needs and preferences, categorized as functions, come to be expressed as behaviors. The term *antecedents*, including what popular culture calls *triggers*, refers to how variables such as an individual's interpersonal situation, environment, and existing skills impact current choices (i.e., behavior). The behavioral concept of establishing operations is parallel to the psychological construct of *motivation*. This concept acknowledges that cognitions, perceptions, and emotional states influence the individual's selection of options from his or her behavioral repertoire. In behavioral theories, an individual's action—the *behavior* in the antecedent–behavior–consequence sequence—is regarded as a purposeful, decisive move to fulfill one or more of five functions. An individual engages in rationally strategizing, recalculating, and manipulating the dynamic tension between opportunity and risk in choices on an ongoing basis. Choices are susceptible to the potent mix of antecedent variables including context, individual's needs, and prevailing peer group dynamics in a process that is willful and fluid.

It is easy to comprehend the function of obtaining desirable tangibles. A paycheck, new car, and favorite food item are common examples of tangible reinforcement. Reinforcers are highly idiosyncratic, such as which car is preferred. One cannot predict with certainty for another individual the value he or she assigns to a particular offering or what that person is willing to do or risk to procure it. Furthermore, one may not understand or agree with another's methods to obtain tangibles. For example, while some offenders engage in criminal acts to get money or other resources, there is a subset of offenders who commit criminal acts to obtain a safe place to shower and sleep, consistent meals, and the medical and mental health care that incarceration provides. While incarcerated, some act out to obtain other tangible reinforcers such as a single cell or transfer to a particular site.

Attention is generally a very powerful motivator for humans, especially now that homemade videos, pictures, web pages, texts, and tweets can be shared with a wide audience in a matter of seconds. These communications are further reinforced when the number of viewings or retexts is also tracked and posted, providing immediate gratification and feedback, which strengthens attention-seeking behavior. As an example of how a function can be expressed through adapting behavior to certain settings, during incarceration the need for attention can be expressed through writing grievances, complaining to an outside entity, engaging in self-injurious acts, or making suicidal threats.

The functional category of escape includes behaviors an individual uses to remove him- or herself from a setting or context in which he or she is currently engaged, such as claiming illness in order to leave a psychotherapy or counseling group early. Similarly, an individual is engaging in the function of avoidance when he or she manages to exclude him- or herself from an activity, such as going to sick call instead of group counseling.

Sensory stimulation is a function that is more difficult to comprehend and study but still is highly pertinent for certain individuals. Perhaps people who frequently engage in fights, seek restraint, and commit self-injurious acts are achieving effective sensory stimulation. In some clinical cases of offenders with abuse history or

borderline personality disorder traits, these behaviors may actually be an attempt to get others to provide physical engagement, which may be soothing on a physiological level.

As an example of a powerful behavior choice which may fulfill multiple functions, consider alcohol and substance abuse, which may provide tangible reinforcement, escape, and sensory stimulation. Substance misuse is implicated in a very high number of offenses that result in incarceration in the United States, including domestic violence, driving while intoxicated, public offenses, and property offenses. Substance use is a particularly complicated choice since offenses may be committed to procure the preferred substance, which then impacts the cognitive functioning and behavioral repertoire of the offender, and the acquired drive state (i.e., addiction) can lead to further criminal behaviors.

Behavioral interventions involve teaching individuals adaptive, prosocial skills. This is done by educating them about the antecedents (internal and external) of their behaviors (e.g., triggers) and manipulating the consequences of their actions as they practice these skills. Positive reinforcement is provided for appropriate performance and withheld for maladaptive behaviors, including those related to breaking the law.

Applying Behavioral Principles to Crime

It is the hallmark of a behavioral approach to utilize data to test and adjust interventions, and newer law enforcement practices of problem-oriented and community-oriented policing are examples of this. Programs such as School Resource Officers and Data-Driven Approaches to Crime and Traffic Safety have strong empirical support. Data-Driven Approaches to Crime and Traffic Safety is a law enforcement approach whereby police use spatial and temporal analyses to decide where to allocate resources, such as parking an unmanned police car near a busy intersection or increasing officers in a high crime area. The increased visibility of enforcement results in more community contacts and better relationships, so effective deterrence is not necessarily correlated with an increase in number of tickets or arrests. From a behavioral perspective, more visible law enforcement serves as a discriminative cue

to prospective offenders to change the cost–benefit ratio of choices. Thus, the basic behavioral principle of the stimulus delta is being applied successfully. This behavioral term refers to a stimulus that indicates that in its presence, a response will not be reinforced. In this case, when a police officer is nearby, a crime does not occur. Research confirms that the visible presence of more policing and equipment decreases the incidence rates of numerous high-profile categories of crimes such as hijacking aircraft and mass shootings. Furthermore, that a successful, well-publicized criminal event is often followed by an increase in subsequent attempts highlights the importance of attention to influence behavior in our culture.

Another basic behavioral principle is that behavior that is positively reinforced (i.e., rewarded) is strengthened and continued, whereas behavior that is punished will be decreased or temporarily suppressed. Overall, punishment of criminal acts is best regarded as conditional in the United States. Since not all crimes result in arrest and punishment, law enforcement and legal processes do not always influence cost–benefit analysis in a predictable way. Inconsistent sentencing, effective defense lawyers, and plea bargains may result in the delivery of intermittent reinforcement, which makes a behavior harder to extinguish. An offender may decide that a crime is worth the prison time if apprehended. The *three strikes* laws (i.e., more permanent punishment for repeat offenders with three or more separate instances of felonious criminal behavior) are examples of intermittent reinforcement, until one experiences that last strike. Often adept at applying behavioral principles themselves, successful criminals change their offending behaviors based on the probability of being caught, perceived profit, and current relevant laws.

Lengthening the time between the act and consequence significantly lessens the strength of the punishment and likely decreases possible deterrence. As a further complication, although mainstream society considers imprisonment, community service, house arrest, and fines to be punishment, these conditions may or may not be costly or aversive enough to the offender to decrease the probability of choosing a criminal behavior. If incarceration, probation, and fines quickly and consistently followed the commission of a crime, recidivism rates would be significantly

decreased. However, incarceration itself may be reinforcing. During detention and incarceration, offenders are provided a structured environment (i.e., fed, provided a bed to sleep in) and have the opportunity to learn from other criminals how to use maladaptive behaviors in a purposeful way, develop strategies to cope in correctional settings better, or set up a network to commit criminal acts more effectively. When this occurs, the likelihood of future criminal behavior increases rather than decreases (i.e., prison becomes criminogenic—increases the likelihood of risk for crime).

The Challenges of Making Data-Oriented Decisions

Federal and state systems sometimes alter laws or sentences in response to particular cases as a result of public outcry, such as with Megan's Law (laws that make it a state and federal requirement to make publicly available information about sex offenders). When more laws are written, there may be unintended consequences. For example, as more offenders are forced onto a sex offender registry, the recidivism rate tends to go up because more individuals are being tracked. When unable to find work or underemployed, with residential options severely compromised, research indicates that the registry hampers returning citizens from effectively reintegrating into their communities. These individuals become increasingly likely to commit subsistence crimes upon release and are then labeled recidivists. Data show that most persons on these registries are not at high risk of reoffending, contrary to the public's beliefs.

Sometimes in response to the well-publicized narrative about particular cases, public opinion motivates legislators to act while available behavioral data are ignored in implementing laws. In addition to the previous example, Scared Straight programs (alternatives to traditional punishment whereby usually young offenders are exposed to conditions of confinement in an effort to *scare them straight*) continue although research has documented that participants become more likely to offend after this programming. There is still a widespread belief that the death penalty is a deterrent, even though research to date has indicated it is used so infrequently and for such specific crimes that this belief is not empirically supported.

Behavioral theory is being utilized successfully in designing and implementing cognitive behavioral programs for incarcerated offenders, although availability and type of programming are highly dependent on the resources and philosophical underpinnings of a particular system. Most states offer some version of cognitive behavioral programming designed to change criminogenic thinking and develop adaptive skills. These programs promote effective choice making, problem-solving, emotional regulation, and stress management. More correctional systems in the United States are also considering use of incentives (i.e., rewards for good behavior) such as good time (i.e., early release from incarceration), residence in a preferred pod, and additional recreation hours. There is a small but growing body of research on the effects of programming inside correctional settings, which has demonstrated that behavioral treatment produces the strongest effect in decreasing misconduct and is correlated with larger reductions in recidivism later.

One of the challenges in measuring the impact of the application of behavior theory to crime is that function of behavior has traditionally been assessed based on individual behavior, whereas crime data are most often studied at the aggregate level of cities, states, and countries. Data are also difficult to collect, analyze, and apply given that many crimes are not reported to police, and punishments vary widely. Behavior theory would predict that when the incentives of better education, decent paying jobs, community mental health services, and safe housing are available, it would stand to reason that crime is less reinforcing as an option.

BI-ADAPTIVE MODEL OF MENTAL ILLNESS AND CRIMINALNESS

The bi-adaptive model provides a framework for intervening when the two areas of mental illness and criminalness occur in the same individual. The presence of multiple problem areas (comorbidity) increases negative outcomes. This has repeatedly been shown in the mental health field, as the level of problems at work, distressed close relationships, and generally poorer health outcomes result when more than one mental health disorder is present. In addition, advances in the treatment of co-occurring, or comorbid, disorders have suggested a unified treatment protocol or a combined/interdisciplinary approach.

Drawing upon the co-occurrence in psychiatry literature, a bi-adaptive model of mental illness and criminalness was developed. This model has implications for research, practice, and treatment. For example, through the proposed treatment matrix of intervention strategies, targeted content areas, and therapeutic processes, the bi-adaptive model outlines an integrated strategy to intervene with offenders with mental illness. This entry first explains the comorbidity framework and then discusses the similarities between the comorbidity framework and the bi-adaptive model, with a focus on offenders with mental illness.

The Comorbidity Framework

The comorbidity framework has been used to discuss the integration of mental illness and criminalness. The comorbidity framework serves as a heuristic, for technically two diagnoses are required for comorbidity and criminalness is not a recognized diagnosis. In contrast to the comorbidity framework, the bi-adaptive model is concerned little with whether the two areas occurred simultaneously or sequentially or whether one area is the cause of the other area—for example, whether criminalness is what contributes to the etiology of the mental disorder (although further etiology developments may inform and modify aspects of the bi-adaptive model).

Functional impairments in offenders with mental illness can lead to difficulties in carrying out basic probation tasks, such as paying fines. These functional impairments may contribute, indirectly, to the relationship between mental illness and recidivism. This is consistent with the literature, which highlight the role that the understanding of a mental illness can have in providing practical suggestions for managing recidivism risk. Some suggestions include supervision strategies to decrease anxiety, perceived threat, and negative affect.

Based on offender samples, the occurrence of a single disorder seems to be rare. Co-occurrence is far more common. In examining the prevalence of comorbidity among offenders, almost all offenders with mental illness diagnosed with common mental disorders (e.g., major depressive disorder, post-traumatic stress disorder, substance use disorder) also have a personality disorder (e.g., antisocial personality disorder, borderline personality disorder, obsessive-compulsive disorder). This was true regardless of the mode of assessment (interview vs. self-report). Similarly, the converse was also true. Those with a personality disorder reported one or more common mental disorders in the past, with 50% having an active mental disorder. When examining psychopathy, there was no evidence that psychopathy was associated with higher level of mental disorders. In summary, there is no single, unique pattern for offenders with mental illness.

Similarities Between Mental Health Comorbidity and the Bi-Adaptive Model

The most basic similarity between the mental health comorbidity framework and the bi-adaptive model is the occurrence of two distinct problem areas within the same person. Using this similarity as a basic starting point, there are other areas of similarity, including increased risk of maladaptive outcomes, need to treat both areas, optimal treatment paradigm, role of substance abuse, and explanatory models.

Increased Risk of Maladaptive Outcomes

A general conclusion of mental health comorbidity is that it results in increased maladaptive outcomes across various domains. With the bi-adaptive model, a similar conclusion can be made regarding outcomes. Offenders with mental illness have increased victimization, have criminal justice outcomes, and demonstrate an increase in maladaptive functioning.

With incarcerated offenders, the co-occurrence of antisocial personality disorder and depression has been predictive of institutional misconduct. What is important to note is that depression, by itself, was not predictive of institutional misconduct, a result that is similar to other research that demonstrates depression is not a strong predictor of criminal justice outcomes. The general antisocial and depression results are also similar to adolescence results, whereby the co-occurrence leads to general maladjustment. In general, the likelihood of maladaptive outcomes increases, but in the case of offenders with mental illness, the stronger conclusion becomes more complex and more cumbersome.

Need to Treat Both Areas

Some researchers have emphasized the need to treat multiple areas simultaneously. Treating both areas simultaneously is the perspective of a common treatment approach of addressing the etiology of two disorders when they co-occur. In addition, it has been found that treatment can have broad effects even when the treatment is addressing a specific disorder. For example, when anxiety is targeted in treatment, other related disorders that are not specifically addressed in the treatment

protocol show improvement. The actual mechanism of change could be the generalizability of the intervention to the various aspects of each disorder or the treatment could be addressing a common and general feature of the *core* features of mood disorders. Based on this conclusion, some researchers suggest a unified approach focusing on emotional regulation and dysregulation.

In the context of the bi-adaptive model, a strong common group between criminalness and mental illness is not explicitly present. But there are aspects of the combined criminalness and mental disorder that would benefit from a unified approach. One area would be adherence to a medication regime. The principles of this specific adherence would be the same for adherence to a parole officer's reporting schedule. Thus, whether the reason is to treat multiple areas simultaneously or to address common aspects of each component of the bi-adaptive model, maximizing intervention efforts appears to occur through a unified approach.

Optimal Treatment Paradigm

An optimal intervention requires integrated strategies. Integration can refer to content integration and systems integration. Similarly, a distinction can be made between systems and services integration, which would include a single intervention plan. Research shows that criminalness has a strong antisocial component. Behavior indicators of antisocialness can be a contributor to noncompliance of medication, missing appointments, and intervention attrition. Medication noncompliance combined with substance abuse has been shown to be associated with violence among psychiatric patients. Thus, addressing an aspect of criminalness—that is, antisocialness—may have benefits for better managing an offender's mental illness.

Another aspect of an integrated approach is the role of social groups. Often, families play a role in the course of mental illness. Efforts have been made to integrate the family into interventions. The goal of this family integration is to increase information about comorbidity, decrease family stress, assist with problem-solving, develop a collaborate approach with the treatment team, and increase social support.

Role of Substance Abuse

Within both mental health and criminal justice areas, substance abuse is a damaging factor, regardless of whether the outcome is of mental health or criminal justice nature. Once a substance use disorder is present, epidemiological studies suggest that the likelihood of a mood or anxiety disorder is 40–60%. Also, epidemiological studies have shown that when included with other predictors, the combination of substance use and severe mental illness will predict violence, when severe mental illness by itself will not. For instance, among patients with schizophrenia, substance misuse will increase the likelihood of serious violent behavior 3–4 fold.

In a comparison of offenders with a single mental disorder and those with an additional diagnosis of substance abuse, those with the dual diagnosis were associated with greater difficulties in social and criminal justice domains. Socially, those with a dual diagnosis had greater use of mental health services and anticipated that they would be homeless upon release. With criminal justice outcomes, those with dual diagnosis were more likely to have a dangerousness assessment, more probation orders, and greater recidivism. Among offenders with mental illness, it is estimated that between 21.7% and 35.0% of offenders were drinking alcohol at the time of their offense. This compares to 15.1% and 30.4% of offenders without mental illness.

Within prison, the prevalence of co-occurrence disorders is greater than the community, regardless of how co-occurring is measured.

BIAS IN CRIME POLICIES AND PRACTICES

Potential biases in crime policies and practices exist across a large number of possible groups and categories, including race, class, age, gender, gender expression, sexual orientation, nationality, and religion. Rather than simple or one-dimensional, the role of bias in criminal justice policies and practices is multidimensional and intersecting, with biases of different origins finding different points to seep into the process and compound one another. For instance, police practices that make it more likely for members of some groups to come into contact with the criminal justice system are compounded by prosecutorial and judicial policies that use prior contact with the criminal justice system as a strike against defendants.

By far the most research on criminal justice bias in the U.S. context has involved race; thus, this discussion focuses on race. After discussing common explanations for disparities in the U.S. criminal justice system, this entry briefly describes the history and sources of racial bias in the U.S. context and then provides a brief overview of what is known about bias in different specific criminal justice policies and practices.

Explanations for Disparities

A person's chances of involvement in the U.S. criminal justice system depend in large part on their race, class, age, and gender. Young impoverished African American men are disproportionately more likely to be involved in essentially all levels of the system. These disparities are easy to see upon even a cursory glance at the data released by the Bureau of Justice Statistics. Less immediately apparent, however, is an explanation for

these differences in the likelihood of criminal justice system involvement. At least three broad types of explanations exist for why disparities in the criminal justice system exist, each pointing to a different source of bias. Each explanation is also more complicated than it initially appears.

One explanation is that agents within the criminal justice system—police officers, lawyers, judges, corrections officers, and others—act in biased and prejudiced ways. This bias may be conscious and intentional, or it may be enacted without conscious awareness that the bias exists. In other words, addressing bias is not as simple as identifying those actors who are acting in obviously and overtly racist, classist, or sexist ways.

A second explanation has to do with crime policies themselves. Laws and the policies through which they are enforced constitute a significant source of bias. Negligent or unethical actions by the wealthy and by large corporations may do more to harm U.S. citizens both economically (e.g., wealth fund managers who take risks with the retirement accounts of others for their own personal gain) and physically (e.g., through pollution or the intentional suppression of information about the negative health effects of products) than do many *street* criminals. Yet, several of these actions are not legally prohibited. Even among actions clearly against the law, existing policies make it more likely that the law will be enforced against some groups rather than others. For instance, as a consequence of living in smaller spaces, poor urban residents tend to be more likely to both purchase and use illegal narcotics in public spaces, while the wealthy—who by self-report measures use illegal narcotics at similar rates—tend to both acquire and use them indoors. Antidrug policies that involve police sweeps of public places, then, will unsurprisingly pick up more poor than wealthy people.

A final explanation is that members of these groups commit more crime. There is some evidence that this is the case for some crimes, and it accounts for some—though not all—of the disproportionalities in exposure to the criminal justice system. However, this story too is not quite as simple as it seems. Research suggests that few biological differences exist across racial lines, especially those that would predict differences in behaviors like crime. Instead, racial differences in

offending are a product of socioeconomic factors largely rooted in the radically different and substantially more disadvantaged contexts in which racial minorities live, the strains caused by historical and contemporary mistreatment, and cultural adaptations to this differential social structure and mistreatment. If crime is a symptom of poverty or inequality, then the social policies that maintain intergroup economic inequalities are also an important source of bias.

History of and Sources of Bias

In perhaps the most famous sociological essay on prejudice, Herbert Blumer suggests that prejudice emerges as a feeling among members of a dominant group toward subordinate groups when two conditions are met: when the members of the dominant group identify with or see their fortunes as depending on the overall status of that group and when they perceive a subordinate group as interested in a greater share of the resources or privileges believed to rightly belong to that dominant group. These feelings help justify the differential treatment of members of these other groups. Dominant groups are likely to use their disproportionate influence over laws and the criminal justice system to ensure status quo group hierarchies—in other words, to ensure that those disproportionately benefiting from the current system continue to do so. Thus, biases that disadvantage members of subordinate groups are likely to emerge when dominant groups perceive their group membership as important and perceive other groups as interested in some of their group's privileges and resources.

As a result, there is a long history of racial biases in the legal and criminal justice systems. The legality of chattel slavery based on race is among the earliest and most egregious, accompanied by a series of complementary justice policies and practices, including the Fugitive Slave Act of 1850. The abolition of slavery during the civil war marked the beginning of a series of openly racially biased policies and practices designed to preserve the existing racial caste system, including the Black Codes and the practice of convict leasing in which many former slaves were imprisoned for *crimes*—enforced by policy or practice only on African Americans—and then sold to companies

desiring their labor, in some cases back to the same plantations from which they had recently been freed. Following this, Jim Crow laws were established throughout the South, legalizing racial discrimination and de jure segregation.

The role of bias and discrimination in these policies and practices is readily apparent: Differential rules or treatment on the basis of race is explicitly mandated or allowed in the laws themselves. These *explicitly* biased policies and practices were challenged and in many cases overturned in the 1950s and 1960s by a series of legal decisions and legislative acts. At the same time, the civil rights movement was changing social norms about race, making explicit and overt animus toward other races less socially acceptable.

Ironically, these successes have also served to obscure the role of bias in policies and practices. Mary Jackman has suggested that dominant groups change the ideology that supports their disproportionate privileges and resources based on whether intergroup inequalities are being effectively challenged. When inequalities are accepted, the dominant group can advocate policies that explicitly benefit them as a consequence of their group membership, as was the case with many racial policies before the civil rights movement. When they are challenged, however, dominant groups adapt their ideology by embracing individualism and eschewing the notion of groups, while simultaneously ignoring that members of different groups may not have equal opportunities based on historical or contemporary discrimination.

Many White Americans were uncomfortable with the social and legal changes sought by the civil rights movement. Some politicians, knowing that explicit appeals to racism were becoming less socially acceptable, began using code words or dog-whistle issues to activate these feelings without explicitly referring to race. Importantly, crime was one such topic, and support for *tough on crime* policies and practices became important components of the strategy to recruit White voters uncomfortable with racial change known as the Republican *Southern Strategy*. The strategy was so successful that Democrats also adopted *tough on crime* rhetoric, particularly in the aftermath of a racially charged political advertisement attacking 1988 presidential candidate Michael Dukakis for

supporting a purportedly *soft on crime* policy (the *Willie Horton* ad).

Relative to earlier eras, in the contemporary era, the role of bias is more difficult to see. A number of scholars have suggested that evidence of continued bias can be seen in support for policies that maintain inequalities even among some who would explicitly deny such motivations. In the area of economic policy, this phenomenon has been described as symbolic, laissez-faire, or color-blind racism. Several scholars have developed *implicit* measures of racial bias, using tests to tap into automatically activated associations or biases that the subject either may not be aware of or may be consciously trying to conceal, even as it is relevant to his or her behavior. In the area of criminal justice practice and policy, research has found evidence of implicit biases among the police in their decisions to shoot, among potential jurors in the decision to convict, and among the general population in their support for harsh punitive policies and practices that are disproportionately applied to racial minorities. Importantly, many of the people holding biases toward Blacks and acting in biased ways would explicitly deny being motivated by bias. This means that understanding and addressing bias in the modern era must begin by dispensing of older notions of bias as something which is explicit and easy to see.

Bias in Policies

Researchers have identified racial bias in a wide variety of criminal justice policies that are purportedly nonracial. The most severe sentencing options added as part of *tough on crime* policies—mandatory minimums, truth-in-sentencing, three-strikes laws—have been disproportionately applied to young Black men. The *war on drugs* has been criticized for targeting the kinds of methods of drug use and distribution in Black communities rather than White communities, most notoriously in the 100-1 crack-to-cocaine sentencing disparity. The *war on gangs* has been accused of a similar bias in focus.

In addition to these policies explicitly focused on criminal justice policies, a variety of other social policies are relevant to understanding bias in the criminal justice system. These include the legal decisions and legislation that ignored de

facto segregation and its consequences while outlawing de jure segregation. This also includes an interlocking system of disparities and bias in a broad system including schools, health care, and the labor, housing, and credit markets, a phenomenon Barbara Reskin has referred to as uber- or meta-discrimination. The disproportionate punishment of people of color is similarly not confined to the criminal justice system: Black students are more likely than White students to be disciplined or suspended as are Black welfare recipients relative to Whites.

Bias in Criminal Justice Practice

Police

The police are often the primary point of contact between the criminal justice system and the public. The police possess a wide power of discretion in where they are deployed, what they investigate, and how they respond or act within situations. By some measures, this discretion exceeds that available to actors at later stages in the criminal justice process, meaning that biases at this stage can have particularly large effects. The result of this discretion is disproportionate levels of police contact, arrest, and mistreatment.

Deployment and spatial strategies are one source of bias on the part of the police. Research has suggested that police tend to focus drug enforcement efforts on open-air drug markets in poor and largely non-White communities. Arrests are easier in this environment, but the result is racial disproportionalities relative to actual law violation. Similarly, research has suggested the police target Black and Latino neighborhoods when conducting stop and frisks and for other enforcement activities. At the individual level, research indicates that Black and Latino pedestrians and motorists are more likely to be stopped and once stopped more likely to be searched than Whites. Research on street stops in New York reports that Black suspects were not more likely to be arrested, suggesting Blacks are *unnecessarily* stopped at higher rates.

In addition to differential exposure to the criminal justice system, bias also results in the differential mistreatment of suspects along racial lines. Black suspects are more likely to be the victims of excessive force charges, and racial and

ethnic minorities are more likely to die in police custody. As a result, racial and ethnic minorities tend to have substantially less faith in the police and be more likely to perceive the police as biased. One paradoxical consequence is that despite the disproportionate levels of criminal justice system contact, minority communities often feel *underpoliced* in that they lack faith in the police's ability to address local crime problems.

Courts and Sentencing

A variety of tough on crime policies have acted to disadvantage Black suspects and defendants at the judicial stage of the justice process. A variety of work has suggested pretrial detention procedures disadvantage racial and ethnic minorities, including public defender programs, the bail system, and prosecutorial decisions.

Juries are also a major source of bias, even when, as in the case of implicit bias, they may not be aware of their own biases. A variety of work has suggested that jurors are less likely to act favorably toward defendants from other racial groups: Defendants are more likely to be convicted and receive harsher sentences including the death penalty when the juries have greater numbers of out-group members. Relatedly, juries are more likely to blame external factors for criminal behavior by in-group defendants but internal factors for the same behavior by defendants of other races. This is especially important given that prosecutors may use peremptory challenges to systematically excuse Black potential jurors, especially in cases involving Black defendants.

Race seems to influence jurors in a variety of subtle ways: They are more likely to interpret ambiguous evidence as being indicative of guilt when a suspect has darker skin and more likely to view prosecution witnesses as being more credible in cases involving Black defendants. Jurors are also more likely to render guilty verdicts and recommend harsh sentences when defendants are accused of committing crimes that are stereotypically associated with their racial or ethnic group.

As a consequence of bias in the judicial stage of the justice process, there are substantial disparities in the punishment meted out by race and ethnicity. This includes imprisonment, which is substantially higher among Latino and especially among Black

men than it is among White men. One outcome of this is that incarceration appears to have devastating consequences for the individuals, families, and communities that experience it, including actually increasing the likelihood of further crime and criminal justice system involvement for the individual who has been incarcerated, for the children of the incarcerated, and for the communities experiencing the highest levels of incarceration. Thus, bias in criminal justice policies and practices acts to sustain future disparities in contact with the criminal justice system.

Bias also appears to play a role in the decision to invoke society's harshest punishment: the death penalty. Both the race of the offender and especially the race of the victim appear to play powerful roles in the decision to invoke the death penalty, with cases involving White victims and Black defendants being the most likely. Latino defendants accused of killing White victims are also disproportionately likely to receive the death penalty. Once again, juries are an important source of bias in this process, as are prosecutors in their decision to seek the death penalty in the first place and in their exclusion of non-White jurors who are less likely to support the death penalty and more likely to give more weight to mitigating evidence.

Finally, there is also evidence of bias in the juvenile justice system, which was another target of punitive reforms during the *tough on crime* era, spurred in part by a popular discussion of the existence of superpredators—a notion that played on racial fears to make predictions about a wave of youth violence that never materialized. Bias and disparities in the juvenile justice system are especially consequential as they are likely to compound over the life course of the juveniles caught up in them.

BIKER GANGS

Biker gangs, also known as *outlaw motorcycle gangs*, are close-knit factions of motorcyclists connected by collective attributes such as deviant subcultural values and norms; a core, hierarchical leadership structure; regulations for joining and successfully maintaining full membership status; an established moniker and other shared trademarks that denote membership (e.g., vests, patches, colors, and mottos); a chosen locale and clubhouse; and a significant, persistent integration of criminal activity into the group through the actions of its members and/or leaders. These enigmatic organizations are interwoven with subcultural norms emphasizing hypermasculinity, unruliness, and a tendency toward violence and other crime that sets them apart from law-abiding motorcyclists and conventional society. As a result of their unique subculture and makeup, biker gangs occupy a distinctive niche within the universe of gang folklore and organized criminal syndicates. Although biker gangs conduct themselves in a clandestine manner, their criminal enterprise has attracted ongoing attention from

law enforcement agencies and sparked a degree of allure within popular culture and the media. This entry discusses general characteristics of outlaw biker gangs, including their prevalence, norms and values, composition, and offending patterns.

Biker Gang Prevalence

Millions of people in the United States own motorcycles and represent a demographic mosaic fused together by people from nearly every background and social class. Whether motorcycles are used as a method of transportation or function as a leisure activity, virtually all riders and their respective associations or clubs behave in a manner consistent with the law. As a result, outlaw biker gangs emphasize the social and ethical chasms that separate them from nondelinquent motorcycle groups and hobbyists. While deviant bikers and groups comprise a small share of motorcyclists in general, an even narrower sliver of riders may become entrenched within particularly illicit organizations that colloquially refer to themselves as *one percenters*; this term embodies the rider adage that 99% of motorcyclists follow the law, while an extremely narrow minority of riders become deeply embedded within antisocial clubs steeped in crime and delinquency.

Influential biker gangs include the Hells Angels, the Mongols, the Bandidos, the Outlaws, the Sons of Silence, the Vagos, the Pagan's, and the Iron Horsemen. The reach of biker gangs is extended by a network of *auxiliary motorcycle clubs* (also known as *puppet*, *satellite*, or *sponsor clubs*), which visibly align themselves with biker gangs that can range from shared social events and displaying the gang's colors to assisting with illegal activities. The National Gang Intelligence Center estimates that as of 2011, a combination of 3,000 outlaw biker gangs and auxiliary motorcycle clubs preside over roughly 44,000 members checkered throughout the United States, with at least 300 organizations solely comprised of one percenters. In addition to maintaining dominion over an array of illicit domestic operations, several one-percenter biker gangs have achieved international ascendancy through black market transactions and violent campaigns in nations such as Canada, Australia, and Mexico and throughout Europe. Outlaw biker gangs have also been known to

work with other criminal organizations to facilitate their criminal activities, including domestic street and prison gangs and international drug trafficking organizations.

Biker Gang Subculture

Aside from a common desire to build fraternal social networks, the subculture of individual motorcycle associations and clubs can vary across several dimensions, including the intensity of group membership, the group's divergence from mainstream, middle-class social standards and goals, and their participation in and endorsement of illegal activities. Scholars James F. Quinn and Craig J. Forsyth note that one-percenter biker gangs tend to prize the archetypal image of a rugged, hardened outlaw living a nomadic existence on the road and on the fringes of society. For individuals in outlaw biker gangs, riding a motorcycle is not simply a pastime; due to the considerable demands implicit in biker gang membership, one percenters can become enmeshed with their chosen clubs, integrating the club and its ideals into fundamental aspects of their identity, social relationships, and worldview. This devotion is solidified through various social decrees from the gang, and, in some cases, an extensive constitution outlining member responsibilities and behaviors subject to sanctions. Club meetings are colloquially referred to as *church* to highlight their importance, and members may be penalized for poor attendance; members are generally expected to pay club dues, attend club events, and frequently ride their motorcycle.

Coupled with the devotion of biker gang membership, the more antagonistic aspects of biker gang subculture can give way to deviant behaviors. For instance, in the social nexus associated with outlaw biker gangs, the concept of respect is a fundamental social currency that is regulated through the threat or use of violence. Countless social affronts are encapsulated within the outlaw biker gang value of respect, and if the behavior of any entity (e.g., a rival gang, a *civilian*, or a fellow gang member) is interpreted as offensive to the gang, it must be redressed through retribution that can escalate to the point of bloodshed. In the context of biker gang rivalries, the pursuit of respect can be a deadly powder keg and amplify intergroup conflicts, creating an ongoing cycle of violence.

Biker Gang Composition

Membership

The overarching theme within the membership base of outlaw biker gangs is one of sameness across race, gender, and motorcycle model. During the late 1940s, outlaw motorcycle gangs were geared toward White male Harley Davidson riders over the age of 21, a trend that has endured. Concentrated racial exclusion prompted the emergence of gangs that permit racial and ethnic minorities, such as the Mongols, who accommodate Hispanic and Latino one percenters, and the Wheels of Soul who accept Black riders. In addition, biker gangs have always been male focused and block women from club business and formal membership, treating them as subservient objects subject to sexual harassment and violence such as *running a train* (i.e., engaging in a succession of sexual acts with various group members). Women formally recognized by the gang as romantically partnered with a male member are referred to as an *Ol' Lady* and are deemed his property, which may sometimes be explicitly stated through a worn patch.

Beyond basic demographic requirements and appropriate motorcycle ownership, it is an extremely difficult undertaking to gain biker gang membership. The process can range from months to years, as membership status is progressively earned by incrementally engaging the gang as a *hangaround* or *prospect*, whereby the applicant demonstrates devotion through grunt work. Once approved by the group's leaders and members, the applicant is formally acknowledged or *patched in* through an initiation ritual and is given full member patches and a vest. Similar to other gang typologies, some of the induction rituals of biker gangs can be viewed as unpleasant to outsiders, such as having their vest sullied by the bodily fluids of other members prior to wearing it for the first time.

Leadership and Organization

Biker gangs are usually governed by a paramilitary-style, hierarchical chain of command, including national and local chapter positions such as a President, Vice President, Road Captain, Sergeant at Arms, and Secretary/Treasurer

controlled through a membership vote. Individual, local chapters tend to be relatively autonomous but are still beholden to a centralized, nationally based leadership body that sets the club's overarching regulations. At the chapter level, leaders generally preside over the more regimented aspects of biker gang membership and maintain the businesslike aspects of the group, such as enforcing the club's constitution, collecting dues and stewarding the club's finances, and tracking club meeting participation. Chapter leaders also guide more systemic forms of illegal enterprise such as weapon and/or drug transactions, direct retaliation against rivals, and mete out punishment to members who violate the gang's protocols. The adoption of paramilitary organizational practices among biker gangs is not entirely surprising, as the founding members of several major outlaw biker gangs were formerly enlisted in the military, and an undetermined amount of contemporary biker gang members have military backgrounds.

Biker Gang Criminality

Collectively, outlaw biker gangs have amassed public and legal notoriety for their enduring participation in contraband distribution, burglary, theft and other property crime, financial fraud, money laundering, prostitution and human trafficking, gambling rings, and both reactive and instrumental forms of violence, ranging from intimidation and assault to homicide. Although one-percenter biker gangs cumulatively engage in a wide assortment of offending, their criminality can be quite complex and multifaceted, as individual chapters and their associated auxiliary clubs can vary in terms of the depth and sophistication of their organizational involvement in crime. Furthermore, due to the inherent social hierarchy of biker gangs, particularly incendiary, antisocial leaders can rapidly steer the gang toward egregious forms of delinquency.

Analogous to other types of gangs and criminal syndicates, precise estimates of biker gang criminality have been limited by difficulties gaining access to biker gangs and data tabulation and sharing procedures for gang-related crime data. Offenses attributed to outlaw biker gangs can range from hostile, expressive crimes, such as spontaneous aggression in response to an affront,

to instrumental and goal-oriented crimes relating to underground markets. Expressive motives occur more commonly in social settings and gatherings (e.g., bars), as these contexts can produce situational conflicts based on machismo, disrespect, and/or the presence of rivals that produce anger and can rapidly escalate into serious, potentially lethal altercations; these conflicts may be spontaneous and isolated but can also be premeditated, such as a planned attack against rivals based on prior clashes. Instrumental offending focuses on generating capital and includes activities such as the production and/or circulation of drugs and weapons, stealing, and prostitution and can also drive conflicts between rival gangs, such as violent disputes over territory linked to illegal operations.

Outlaw biker gangs continue to pose difficulties for law enforcement agencies, as these groups continue to evolve to evade detection. Biker gangs have also been notoriously difficult to litigate, as the deep-seated loyalty and allegiance of biker gangs serves as a barrier against legal intervention. Prolific members, such as the Hells Angels' founder Sonny Barger and former Mongol president Ruben "Doc" Cavazos, have only been prosecuted through the Racketeer Influence Corrupt Organizations Act, which allows ringleaders to be held criminally liable for instructing their subordinates to conduct illegal activities, even if they do not participate themselves. However, Racketeer Influence Corrupt Organizations and other criminal litigation have seen mixed success when applied to biker gangs. Furthermore, the modus operandi of modern biker gangs has shifted toward increased subtlety and no longer publicly identify themselves through worn clothing to evade law enforcement and preserve their criminal enterprises. To this end, some biker gangs, such as the Hells Angels, are outwardly insistent that their organizations are prosocial fraternal groups and have attempted to reshape their scandalous public image through charitable activities and a positive social media presence.

BIPOLAR DISORDER IN INCARCERATED OFFENDERS, TREATMENT OF

Bipolar disorder is a psychiatric illness that is colloquially known as *manic-depressive disorder*. Previous editions of the *Diagnostic and Statistical Manual of Mental Disorders* categorized bipolar disorder as a mood disorder; however, the fifth edition of the *Diagnostic and Statistical Manual of Mental Disorders*, published in 2013, assigned bipolar disorders its own category and aptly places it between psychotic disorders and depressive disorders as it shares features with both of those categories through different phases of the illness. In the United States, since the Community Mental Health Act was passed in 1963, there has been a trans-institutional shift in the

severe and persistent mentally ill population, and the correctional setting has seen a consistent influx of inmates with serious mental illnesses including bipolar disorder. Furthermore, incarcerated offenders with bipolar disorder frequently present with higher severity and complexity of symptoms compared to patients with bipolar disorder in the community setting. Management of their illness presents a unique challenge to the correctional clinicians and requires distinct treatment strategies.

This entry highlights some of the key features in identifying and treating bipolar disorder in incarcerated individuals.

Epidemiology and Comorbidities of Bipolar Disorder in Incarcerated Offenders

Based on nationally represented samples, an estimated incidence of bipolar disorder is 1% in the United States. In comparison, the National Commission on Correctional Health Care reported rates of bipolar illness as high as 4.3% in the U.S. prison population. Studies conducted in community settings have shown that individuals with a history of incarceration had twice the prevalence of bipolar disorder when compared to those in treatment without a history of incarceration. Furthermore, the rates of recidivism are substantially higher in individuals with history of bipolar disorder. These individuals have greater than 3 times the likelihood of a history of four or more past incarcerations when compared to those without a mental health history in the correctional setting. The reemergence of socioeconomic factors, lack of care in the community, and lack of supports and stable relationships all contribute to reoffending and decompensating psychiatrically.

Incarceration can be either the consequence of or a precipitating factor to an individual's psychiatric decompensation. This bidirectional relationship between incarceration and bipolar disorder can be further perpetuated by increased vulnerability to perceived traumatic experiences. This can heighten the distress these individuals experience within the correctional setting, making it harder to treat the underlying bipolar disorder. It is prudent for correctional clinicians to be aware of the comorbid diagnoses that present with bipolar disorder as comorbid diagnoses shape not only the treatment while incarcerated but also the prognosis and chances of

recidivism. Substance use disorders and addictive disorders are the most common co-occurring disorders seen in patients with bipolar illness. Anxiety disorders confer a lifetime risk of 85–90% in these patients, and there is a 7-fold lifetime risk of being diagnosed with intermittent explosive disorder. There is also an increased risk of having a coexisting personality disorder, particularly antisocial personality disorder and borderline personality disorder, which require additional treatment strategies. Studies have documented higher rates of suicide in correctional facilities compared to that in the general population. Notably, incarcerated offenders with bipolar illness have a higher suicide risk compared to other incarcerated offenders.

Factors Affecting Treatment of Bipolar Disorder in Incarcerated Offenders

Bipolar disorder can present in many different phases (manic, hypomanic, depressed, and mixed), and each one can present significantly different than another. It is imperative that correctional clinicians obtain a thorough longitudinal history from the individual as well as by reviewing past records. A diagnosis of bipolar I disorder requires at least one manic episode over the course of an individual's lifetime. A manic episode is characterized by a period of at least 1 week of abnormally and persistently elevated, expansive, or unusually irritable mood, which clients describe as feeling *very hyper* or *on top of the world*. In order for a manic episode to be diagnosed, three or more of the following symptoms must also be present (in addition to the abnormally elevated, expansive, or unusually elevated mood):

- unusually elevated self-confidence to marked grandiosity, sometimes reaching delusional proportions
- decreased need for sleep without any feelings of tiredness despite lack of sleep
- rapid, pressured, loud speech that is difficult to interrupt. In some cases, such speech is angry/hostile or incomprehensible.
- feeling easily distracted and unable to screen out irrelevant stimuli in the surrounding environment
- racing thoughts and explosion of ideas and experiencing an inability to keep up with these thoughts and ideas

- abnormal and persistently increased engagement in goal-directed activities with little regards for sleep or rest (e.g., staying up late at night cooking or cleaning or engaging in multiple projects simultaneously but not able to finish those due to lack of time and organization) or feeling unusually agitated
- heightened engagement in pleasurable activities with significant and painful consequences such as reckless driving, unusual sexual behaviors, and buying sprees

Most importantly, these symptoms and disturbances should cause marked impairment in social or occupational functioning.

Functional impairment in the correctional setting can manifest in many ways. Irritability can cause agitation or violence for seemingly trivial things, grandiosity and impulsivity leading to rule violations and engaging in unsafe situations, sleep disturbances resulting in late night or early morning disruptions. Having a multidisciplinary team to identify patterns of behaviors and symptoms becomes a crucial aspect of making an accurate diagnosis based on the entire clinical presentation. Particularly early in incarceration, it is important to identify primary and secondary diagnoses and clearly establish working diagnoses. Symptoms can be a part of multiple diagnoses, and the clinical picture evolves over time. Substance withdrawals, adjustment difficulties, agitated unipolar depression, and complex trauma can all be misdiagnosed as bipolar disorder. Standardized measures for diagnoses, such as the Structured Clinical Interviews for Diagnostic and Statistical Manual of Mental Disorders, can help provide accurate diagnoses but require significant time and resources. Continuous reassessment of symptoms and diagnostic reevaluation throughout the treatment process helps to establish accurate diagnoses, identify contribution of comorbidities to the clinical presentation, and determine response to treatment.

Management of Incarcerated Offenders With Bipolar Disorder

Managing bipolar disorder in any setting ideally includes a combination of medications, therapy, and behavioral interventions. Generally, the

combination treatments have shown to be more effective than each treatment individually. Management of bipolar disorder in incarcerated offenders frequently requires both pharmacotherapy and psychotherapy due to higher severity of their illness compared to their counterparts in the community, multiple comorbidities, and difficult psychosocial factors. Treatment considerations typically account for the following factors:

- psychiatric and medical comorbidities
- risk of suicidality
- rule out pregnancy (due to risk of birth defects with several psychotropic medications used to treat bipolar illness)
- substance use comorbidities and impact of substance-related withdrawal symptoms on bipolar symptomatology
- environmental factors in the correctional setting (e.g., routines/structure of the correctional setting and/or triggers in the correctional setting that may exacerbate emerging bipolar episodes such as conflicts with fellow inmates or correctional staff)
- psychosocial factors in the community (e.g., relationships, support) with positive or negative impact on symptomatology during incarceration
- past psychotropic medication regimens in the community
- psychotherapeutic modalities used to manage an individual's illness in the community
- past medication trials, efficacy, side effect profiles, and risk–benefit ratio
- potential pharmacokinetic and pharmacodynamic drug–drug interactions, especially when an individual is receiving multiple psychotropic and/or nonpsychotropic medications
- risk of abuse and diversion of prescribed medications
- potential barriers for accessing certain medications (usually newer medications) upon release to the community

Pharmacotherapy

Similar to the community setting, several medication classes are used to treat bipolar illness in incarcerated offenders. These include antidepressants, mood-stabilizing medications such as

lithium, anticonvulsants and antipsychotics, anti-anxiety medications such as benzodiazepines, and sedating medications such as trazodone. Medications simultaneously targeting bipolar symptomatology and substance-related withdrawal symptoms (e.g., divalproex sodium) play a critical role in the management of bipolar illness in the correctional setting. This is due to high prevalence of comorbid substance use in these individuals.

Inmates with significant history of comorbid substance use experience substance-related withdrawal symptoms immediately following incarceration. These symptoms can serve as a trigger and exacerbate their bipolar and other comorbid psychiatric illnesses. Difficulties adjusting to the correctional environment may further complicate symptomatology. Management of symptoms in these individuals requires short term, heightened symptomatic management with mood stabilizers, anxiolytics, and, in some cases, antipsychotic medications.

Frequently, simultaneous implementation of substance withdrawal protocols is necessary. This complex symptomatology usually improves after resolution of acute substance withdrawal symptoms and adjustment to the correctional environment. However, many of these individuals continue to experience chronic substance-related anxiety symptoms and cravings during their incarceration. Incarcerated offenders with bipolar illness have high rates of treatment-refractory symptomatology compared to patients with bipolar illness in the community setting.

Certain psychotropic medications are associated with serious medical consequences. For example, atypical antipsychotic medications can increase the risk of diabetes and cardiovascular illness. Because of the complexity of symptomatology, incarcerated offenders with bipolar disorder frequently receive multiple medications or medication classes to manage their illness. This is partially driven by the initial period of acute and complex symptomatology, requiring symptom management using multiple medications. It is important that correctional clinicians continuously reassess symptomatology and optimize medication regimens, especially after the initial period of symptom management and resolution of substance withdrawal symptoms.

Optimization of medications should be driven by symptoms as well as risk–benefit ratios of medications. Algorithm-driven treatment of bipolar disorder can lead to improved clinical outcomes and reduce polypharmacy by optimizing utilization of evidence-based medications. Adaptations of such treatment algorithms reduce inappropriate variations in clinical practice, reduce costs, and improve patients' quality of life. In general, use of medications with high addictive potential should be minimized due to high prevalence of substance use comorbidities and vulnerability to addictions in these individuals. Evidence has demonstrated effectiveness and benefits of algorithm-driven treatment of bipolar disorder while working within correctional formulary restrictions.

Psychotherapy

Psychotherapeutic treatments play an important role in the management of bipolar illness in the correctional setting. They can help manage psychosocial distress, the initial despair of incarceration, and adjustment issues to the correctional environment; improve coping skills; and address circadian rhythm disruption. Specific psychotherapies, such as cognitive behavioral therapy and dialectical behavioral therapy, have been adapted to treat incarcerated offenders with serious mental illness. Both individual and group therapy can be beneficial, especially as adjunctive treatments to pharmacological management. Relapse prevention and dual diagnosis psychotherapeutic treatments also play a critical role in the management of incarcerated offenders with bipolar illness.

Transitional Planning

When an inmate with serious mental illness is ready to be transitioned back to the community, it is imperative that they be set up with ongoing treatment and psychosocial supports in the community. This is especially critical for inmates with bipolar illness due to high rates of recidivism of these individuals. Successful reentry and integration of these individuals in the community can reduce reoffending. It is likely that the structure of the correctional setting is therapeutic through its organization and management of daily needs (e.g., food, clothes, finances). Upon release, a number of

socioeconomic factors, complex support systems, and limited access to care can contribute to a decompensation and reoffending. Having immediate follow-up and ensuring ongoing continuity of care to adjust treatment as new stressors arise can help stabilize their illness and reduce rates of recidivism.

Incarcerated offenders with bipolar illness present a unique challenge to the correctional clinicians. In addition to the standard treatment approaches used to manage bipolar illness in the community setting, the unique issues with this patient population require distinct management strategies. Use of evidence-based treatments including certain treatment strategies specifically adapted to the correctional setting can substantially improve management of their illness in the correctional setting.

BLACK GUERRILLA FAMILY

The Black Guerrilla Family (BGF) prison gang is one of the most politically revolutionary prison and street gangs in the United States. It has evolved into a highly sophisticated criminal enterprise that not only controls criminal activities inside prison walls but also controls street gangs operating outside prison walls. It is one of the most violent, federal racketeering enterprises in the United States. This entry reviews the background, evolution, and philosophy of the BGF.

Background

The BGF emerged in 1966 at San Quentin State Prison in California. The BGF's founder, George Jackson, organized the gang as a show of opposition to the prison's injustice toward Black inmates and as an effort to provide protection for Black inmates from other prison gangs such as the Aryan Brotherhood. He recruited prison gang members, advocating that their crimes were merely acts of survival in a White-dominated, capitalistic society. He further argued that the legal system was stacked by a White capitalistic government in an attempt to suppress and keep black at the bottom of the socioeconomic status levels. As of 2017, approximately 500 BGF prison gang members oversee an estimated 50,000 members of allied criminal street gangs throughout the United States.

Prior to incarceration, Jackson was a member of the violent Black Panther Party. In prison, he specifically recruited gang members from the Black Panther Party, the Black Muslims, and the Republic of New Africa to join what was then called the *Black Family* or the *Black Vanguard*. In the 1960s, the Black Family merged with the Black Panther Party and the Black United Movement to form what is now called the BGF.

Revolutionary Political Philosophy

The BGF is anti-White and considers law enforcement, correctional officers, and the U.S. government as enemies. All BGF members must be African American. As one of the most politically oriented prison gangs in the United States, the BGF subscribes to a blend of Karl Marx's and Vladimir Lenin's political ideology.

Marxism is an economic, social, and political philosophy that advocates revolution and forceful overthrow of class structures to establish a dictatorship of the proletariat workers called *socialism*. Through this class struggle, Marxists believe that society will develop from bourgeois oppression under capitalism to form a classless, socialistic society. This socialistic society governs without a governing class or structure to ultimately create the foundation for a communistic society.

Similarly, Leninism advocates the democratic organization of a revolutionary vanguard party that will advance a dictatorship of the proletariat class as political prelude to the establishment of socialism. Its founder, Vladimir Lenin, advocated political insurrections, the overthrow of capitalism, and establishment of a socialistic society that would ultimately evolve into communism. As stated by Lenin, "The goal of socialism is communism." He was a Russian communist revolutionary who led the Bolshevik revolution and later became Chairman of the Council of People's Commissars of the Russian Soviet Federative Socialist Republic.

In that the BGF prison gang subscribes to a blend of Marxist-Leninist revolutionary philosophy, it openly advocates the use of violence in the class struggle to overthrow the White-dominated, bourgeois capitalistic U.S. government. This economic class struggle is believed to be the political reform platform that will lead to revolution and the eventual development of a classless society leading to socialism and ultimately communism. The prison gang's stated goals are to

- maintain dignity in prison,
- overthrow the U.S. government, and
- eradicate racism.

This revolutionary, antiestablishment political philosophy serves to create an *us against them* mentality. Prison officials and the U.S. government

are against African Americans, and the BGF is antiprison, antiestablishment, and antigovernment. This *us against them* mentality serves to create solidarity among African American inmates. It also unites BGF members in the political war against prison control and oppression by the capitalistic U.S. government.

Violence and Revolutionary Goals

In the *us against them* conflict, the BGF is willing to use asymmetrical violence to overcome prison control and government suppression. In fact, the name itself, Black Guerrilla Family, is revolutionary based and infers the use of guerrilla warfare.

For example, FBI records reveal that the BGF advocates the use of knives, guns, and guerrilla tactics to bring about the overthrow of the U.S. government. This antiestablishment and antiprison mentality is reflected in the BGF gang's signature tattoo—a tattoo of a black dragon overcoming a prison or a prison tower. Another favorite tattoo is BGF tattooed over a rifle crossed with a bloody sword. Even more tattoos, such as crossed sabers and a shotgun, further represent the prison gang's willingness to use violence against prison officials to achieve their revolutionary goals.

Oath

As noted, the BGF prison gang is openly militant. Members must subscribe to a "blood in, blood out" death oath that requires loyalty to the prison gang for life. The oath sets forth, on five occasions, that the penalty for disobedience or disloyalty to the BGF Code of Conduct includes sanctions such as fines, physical beatings, stabbings, and death. This "blood in, blood out" oath reads as follows:

If I should ever break my stride, or falter at my comrade's side,

This oath will kill me.

If ever my word should ever prove untrue, should I betray the chosen few,

This oath will kill me.

If I submit to greed or lust or misuse the people's trust,

This oath will kill me.
 Should I be slow to take a stand or show fear of
 any man,
 This oath will kill me.
 If I grow lax in discipline, in time of strife refuse
 my hand,
 This oath will kill me.
 Long live the spirit of comrade George Jackson,
 Long live the spirit of the Black Guerrilla Family.
 (FBI Director, 1980)

The oath also references Marxist and Leninist political philosophy. The term *comrade* is referenced in the first sentence, and founding member George Jackson is referenced as *comrade George Jackson*. In this context, the word *comrade* references a fellow socialist or communist who subscribes to Marxist or Leninist political ideology. These terms evidence the BGF's open support for overthrow of the U.S. government and establishment of a communistic society.

BGF members must also memorize and recite a "Death Oath" affirming the "struggle to eradicate the evils and injustices bestowed upon the masses by the despotic ruling classes" and calling for the "uncompromising destruction" of Western civilization. The oath of membership concludes with an acknowledgment that "an oath is a sacred pledge that binds a guerrilla for life" (FBI Director, 1980).

Evolution Into a Criminal Enterprise

Even today, the BGF prison gang advances Marxist and Leninist political ideologies. However, the BGF is now focused on profitable gang-related criminal enterprises. This is especially true for BGF members who operate outside prison walls. On the streets, the Marxist-Lenin political revolution has been moved to the back burner. Gang-related criminal activities, such as trafficking in narcotics, have taken over the front burner. The BGF has moved from its foundation of political revolution to extremely sophisticated criminal enterprises that transact drug-trafficking and gang-related criminal operations on national and international levels.

Surprisingly, many of these street crimes are controlled from inside prison walls. In return for protection services for incarcerated street gang

inmates, the BGF prison gang requires *taxes* (percentages of gang-related profits) from allied street gangs. If an allied street gang refuses to pay taxes, the BGF merely issues a *green light* requiring all prison and allied street gangs to harass, physically abuse, and even murder members of the noncompliant street gang.

Psychological Power and Control

The psychological power and control exerted by the BGF prison gang is enormous. Through the protection racket, the BGF is able to control criminal activity that occurs both inside and outside prison walls. One such example occurred in 2008 when BGF member Travon White entered the Baltimore City Detention Center. White was able to bribe or threaten correctional officials to the degree that he maintained an office, fully equipped with computers and cell phones, while incarcerated. In addition, White controlled which inmates received working positions, cleaning cells and preparing food. This facilitated smuggling operations for tobacco, cell phones, heroin, crack, and marijuana with impunity from correctional facility rules and regulations.

While incarcerated, White had ongoing sexual relations with four female correctional officers and fathered five children by the female correctional officers. One correctional officer provided home-cooked meals each day, often including lobster and wine. Another female officer had "White" tattooed on her wrist and another had White's name tattooed on her neck.

In essence, White was able to run the prison by bribing correctional officers through paying rent and giving gifts such as a Mercedes-Benz to correctional officers. One female correctional officer testified she received US\$16k a week for her services.

The Baltimore correctional facility became a *mini-city* with its own culture. Unlike the neighborhood low-income housing facilities, it had heat, electricity, clean beds, cell phones, snacks, three hot meals a day, cable television, and video games like PlayStation Basketball. It even afforded employment opportunities whereby inmates controlled gang-related criminal operations on the streets. As stated by former Baltimore Police Department Commissioner Anthony W. Batt,

“We’re arresting people and sending them right into the den of that gang haven. We’re basically helping them (the BGF Family) recruit by arresting people” (Marimow & Herman, 2013).

In 2013, White and other BGF members, along with 13 prison guards at the Baltimore City Detention Center, were indicted on federal Racketeer Influenced and Corruption Organizations Act conspiracy charges that included trafficking in controlled substances, battery, threats of violence, intimidation, extortion, bribery, armed robberies, money laundering, retaliation against witnesses, and obstruction of justice. Thirteen prison guards were charged with helping the BGF run a drug-trafficking and money-laundering operation at the detention center. Because of a plea bargain, White, the kingpin of the BGF jail gang, received only 12 years in prison followed by 3 years of unsupervised release.

Organization and Structure

As noted, the BGF subscribes to a Marxist-Leninist political philosophy. The command structure consists of a Central Committee, Field of Generals, Captains of Security, Captains of Arms, Captains of Squads, Lieutenants, and Soldiers. At the bottom of the command structure, the Soldier is any inmate who is willing to align with the BGF and fight for BGF principles. Since the BGF is a prison gang, there is a never-ending source of Soldiers as new inmates arrive on a daily basis.

Any attempts to dismantle the BGF by transferring prison gang members to a different prison are seldom successful. Instead of dismantling the prison gang, relocation merely provides a new location to establish a BGF prison gang set. As stated in the BGF oath, the transplanted BGF gang member is duty bound to assume the position of Regional General, create a new BGF prison gang at the relocation prison, and attempt to maintain contact with the BGF prison gang in the former prison. This serves to further spread BGF prison gang political philosophy from one prison to another.

Psychological Control Over the BGF Soldier

The BGF provides protection for members from predatory inmates, social support, a sense of

belonging, access to smuggled prison contraband, and even opportunities to have sex with prison guards or visitors while incarcerated. The contraband includes access to alcohol, drugs, cigarettes, cell phones, and even video games.

Membership in the BGF prison gang also generates a sense of power and control, both inside and outside prison walls. This enhanced power and control combined with a sense of self-identity replaces the isolation and removal of self-worth that occurs when one is issued a number, prison clothes, and relocated to a prison cell. It also serves to psychologically bond the new member to more veteran prison gang members.

Consequently, the gang becomes paramount in the gang member’s life. The disciplinary beliefs of the BGF are as follows:

- The individual is subordinate to the family.
- The minority is subordinate to the majority.
- The lower level is subordinate to the higher level.
- The entire membership is subordinate to the Central Committee.

The BGF constitutional section on Exemplary Punishment sets forth a death sentence to any member who disobeys the constitution, rules, and disciplinary beliefs of the gang. Without provisions for due process, the constitution states “the Generals, for security reasons, may order and have a sentence of death carried out against a member for violation of one of the above laws” (FBI Director, 1980).

Alliances

The BGF allies with politically oriented groups or criminal gangs that share similar revolutionary philosophies. The BGF also allies with criminal street gangs that serve to enhance drug distribution routes or other gang-related criminal activities. These allies include the Black Liberation Army, Gangster Disciples, the Symbionese Liberation Army, Nuestra Familia, the Weather Underground, and many other African American street gangs (e.g., Bloods, Black Gangster Disciples, Crips). The BGF also aligns with the Hispanic Nuestra Familia when it is beneficial for smuggling or drug operations.

Adversaries

The BGF's written constitution clearly identifies the Aryan Brotherhood and the Mexican Mafia (EME) as enemies. In fact, the constitution identifies the Aryan Brotherhood and the Mexican Mafia as *tools* of the American correctional system that serve to suppress the African American society. In addition, the BGF considers the American Mafia and the Texas Syndicate to be enemies.

BLOODS

The Bloods is a street gang that originated in South Central Los Angeles, CA, in the early 1970s. Bloods are identified by the red color worn by the members of the gang and are known for their long-standing rivalry with another street gang *Crips*, who are identified by the color blue. Along with the Crips, the Bloods are one of the most notorious street gangs in the United States. This entry reviews the Bloods' history, symbology, rivalry with the Crips, and involvement in the drug trade.

Early History

In the 1960s, the political organization the Black Panthers inspired Black youth to seek out unity and respect. After the Black Panthers were weakened in 1969, a group of young Black men in Los Angeles—looking for protection and belonging—created the Crips. The Crips grew rapidly, using force and violence to secure their dominance in the neighborhoods of Los Angeles. In an effort to strike back against the Crips and the violence the Crips were unleashing within Los Angeles neighborhoods, a rival gang, the Bloods, was created.

In 1972, Sylvester "Puddin" Scott and Vincent Owens formed the Pirus Group out of Centennial High School in Compton. The Pirus Group was originally associated with the Crips. However, after facing hostility from several neighboring Crips *sets* (the specific chapters or divisions of the gang), members of the Pirus Group severed all ties with the Crips and formed their own gang—now known as the *Bloods*. The name, the Bloods, was reference to *Blood*, the nickname for street gangs who were not affiliates of the Crips. The members of the newly formed gang adopted the color red to differentiate themselves from the Crips—who wear blue.

Later, Tuemack “T” Rodgers, founder of the Black P Stone Bloods, set out to combat the Crips’ expansion within Los Angeles neighborhoods. He called a meeting, at Manual Arts High School, where four gangs agreed to join together, believing there would be safety in numbers. Smaller gangs in the area, such as the Brims, Athens Park, and the Black P Stone Bloods, merged with the Bloods with the intention of protecting their neighborhoods and their families from the Crips.

The Bloods’ membership was much smaller than that of the Crips and continues to be so. As a result, the Bloods rely on a sense of unity and loyalty among members. Once a person joins a Bloods set, he is in that set for life; a person cannot get out or flip (switch) to another set without his blood being shed (a saying referred to as *blood in, blood out*). Because of its strong rivalry with the Crips, the Bloods evolved into a gang involved with violence, drugs, and lives of crime. As of 2018, there are roughly 70 sets in the city of Los Angeles as well as a significant presence of Bloods sets in New York City, known as the *East Coast Bloods* (or the United Blood Nation), which originated in the early 1990s. The sets are often differentiated by the names of neighborhoods or streets the members are from or live on.

Many of the men in the gang grew up in poor, single-parent households and witnessed firsthand drug addiction and the effects it has on families and neighborhoods. Joining the Bloods allowed such men the opportunity to form a brotherhood with other men in their community—something that they may not have experienced before.

Symbology

Because of the various sets, the Bloods have multiple gang indicators to identify themselves and other members. Members wear red articles of clothing such as T-shirts, bandanas (also referred to as *flags*), jewelry, handmade beaded necklaces, and other apparel. As representation of the *right side*, Bloods may wear their flag on the right side, their hat tilted to the right, or their right pants leg rolled up. Most members have one or more gang-related tattoos or brandings that signify rank, leadership, set affiliations, and years of involvement in the gang. One of the most well-known Bloods tattoo is a *dog paw*, referred to as *triple o’s*, given

to many members upon initiation, and made with the barrel of a gun. Other tattoos include five-pointed stars, crowns, weapons, tears/blood drops, pit bulls, the set name, or the word *blood*.

Hand signs are used as a form of communication between members to greet each other, signify warnings, or intimidate other gangs and nongang members. These hand signs include, but are not limited to, *blood* spelled out in the five-pointed star, the letter *B* and the letters *CK* (meaning Crips killer). Bloods members also engage in gang graffiti, which can be used to disrespect members of another gang or claim territory.

Along with hand signs, tattoos, and graffiti, Bloods use a distinct dialect when engaging with each other. Popular gang sayings include *Krab* (a derogatory name for the Crips), *CK* (Crips killer), and *SuWhoop* (a greeting among Bloods). Bloods also replace most of the letters *C* in words with *B*. YG, also known as *Young Gangster*, is a rapper who joined the Bloods in 2006 at age 16. He is known for his song lyrics and titles that replace the letter *C* with *Bs*. For example, some of his song titles include *Bool*, *Balm*, & *Bolcollective*, *Too Brazy*, *Bompton*, and *Bool*. Another example of Blood symbology in modern culture is rapper Cardi B and her outward display of affiliation with the gang. She regularly wears the color red and replaces the letter *C* for *Bs* in her music. For example, some of her song titles include *Binderella* and *Bartier Cardi*. These examples show that the Bloods’ culture continues to be prevalent in modern-day society.

Rivalry With the Crips

During the 1980s and 1990s, gang violence in Los Angeles increased significantly. From 1985 to 1990, there were 2,682 gang-related deaths, twice as much as in the previous 5 years. Physical fighting was replaced with the use of guns and drive-by shootings. If a gang killed or jumped a member of an opposing gang, retaliation was certain to occur. Gangs were expected to seek revenge on those gangs that attacked them first. In 1984, Keith Fudge, a Bloods member known as *Ace Capone*, was attacked by members of the Crips. He was sitting in his car with two friends when a group of Crips approached the car, held him and the other Bloods at gun point, and stole the car. Staying true

to the gang's rule of retaliation, Fudge and the other gang members later found and attacked a house party being hosted by the Crips. Armed with a shotgun and rifle, the Bloods opened fire on the house and all of those inside; five people were killed, including two Crips members and a 13-year-old girl. This incident became known as the *54th Street massacre* and was the beginning of a new era of fighting between the Bloods and the Crips.

In the spring of 1991, motorist Rodney King was video recorded being beaten by White Los Angeles police officers. When the officers were acquitted of using excessive force in 1992, riots broke out in the streets of Los Angeles. The Bloods and Crips, along with other rioters, looted stores and engaged in other sorts of chaos throughout the neighborhoods. Over the next several days, 54 people were killed. In response to the loss of life in such a brief span of time, the gangs decided to call a truce. This agreement to keep peace between the gangs only lasted 3 months.

In the year following the truce, the gang-related death toll dramatically increased. In 1993, on Halloween (October 31), in Pasadena, CA, a member of the Bloods was gunned down on the street by members of the Crips. To avenge their fallen gang member, a group of Bloods began searching for the Crips responsible. The Bloods saw figures walking in the dark and opened fire—rather than firing upon rival gang members, the Bloods fired on a group of 11 young boys out trick-or-treating for Halloween, killing three of them. This incident is now referred to as the *Halloween massacre*.

Drug Trade

In the 1980s, gang members began to drift away from typical gang life toward drug dealing as a means of funding. Access to the large amounts of money possible from the drug trade led to the ability to purchase higher tier weaponry, which in turn led to more violence. Thus, violence between the Bloods and the Crips increased as the fighting shifted from protecting neighborhoods to claiming and controlling turf for drug trading. In 1987, violence was so high, there was one gang murder every 24 hr in Los Angeles.

As gang turf wars became more frequent, gang violence began to seep into other neighborhoods, resulting in the death of innocent victims. For

example, on January 30, 1988, Karen Toshima, a graphic artist from Long Beach, CA, was murdered after having dinner with a friend. She was shot after being caught in the crossfire between two gangs. It has been argued that the introduction of gang members into the drug trade has changed the original structure of gang life, leading to more murders and more fights with life-threatening consequences.

BORDERLINE PERSONALITY DISORDER

Borderline personality disorder (BPD) is one of four Cluster B personality disorders in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*—the others being antisocial personality disorder, histrionic personality disorder, and narcissistic personality disorder. The term *borderline* was first introduced in 1938 to describe patients not easily classified as psychotic or neurotic. BPD affects 1–2% of the general population

and is the most common personality disorder in clinical settings, present in up to 10% of psychiatric outpatients and 20% of psychiatric inpatients. The condition is also overrepresented in prison samples, with estimates ranging between 25% and 50%. Given the seriousness of this condition, in 2008, the U.S. House of Representatives unanimously passed a resolution calling May the BPD Awareness Month. This entry reviews the symptoms, diagnosis, etiology, and treatment of BPD.

Symptoms of BPD

There are two hallmark characteristics of BPD in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*: widespread instability covering emotions, relationships, and self-image; and impulsivity. Other classification systems have grouped BPD symptoms into four distinct variables: affective disturbance, disturbed cognition, impulsivity, and intense/unstable relationships. Most formal factor analytic work suggests between 1 and 3 constructs underlying BPD symptoms.

The symptoms of BPD are operationalized as nine distinct criteria of which an individual must meet five in order to be diagnosed. First, individuals with BPD are hyperconcerned that others will abandon them, which stems from a significant fear of being alone. Second, individuals with BPD exhibit extreme and unstable relationships and vacillate between unrealistic over- and undervaluing of others. Third, individuals with BPD have an unstable sense of self. Fourth, they display impulsive behavior in at least two areas. Fifth, individuals with BPD often have a history of suicidal behavior (e.g., threats, gestures, attempts) or self-injurious behavior (e.g., cutting). Sixth, individuals with BPD present with highly unstable mood and affect. Seventh, chronic feelings of emptiness are often present. Eighth, individuals with BPD often have problematic displays of anger (e.g., physical fights). Finally, individuals with BPD may experience episodic paranoia and/or dissociative symptoms.

Diagnosis and Assessment of BPD

BPD is overrepresented in females. Recent studies suggest that the rate of BPD in incarcerated females ranges from 20% to 54%. The rate of BPD in incarcerated males approaches 25%,

suggesting that the condition is significantly overrepresented in prison populations among both genders. In order to be diagnosed with BPD, an individual must first meet criteria for a general personality disorder. In brief, an individual must display a consistent set of thoughts, emotions, and/or behavior that falls outside the realm of normalcy given an individual's particular culture. At least two broad areas of functioning from the following categories must be affected: thinking, emotions, interpersonal functioning, and impulse control. This pattern of behavior must be inflexible, be impairing, appear by early adulthood at the latest, and occur across a broad spectrum of situations. Once an individual meets the general personality disorder criteria, he or she may be diagnosed with BPD if five of the nine criteria previously discussed are met.

Assessment of BPD is most often made through a detailed clinical interview that probes an individual's history and current/past functioning. Widely used psychological tests such as the Minnesota Multiphasic Personality Inventory, Millon Clinical Multiaxial Inventory, and Rorschach all purport to assist in diagnosing BPD.

Etiology and Course of BPD

As with most complex conditions, BPD is considered multifactorial in nature and is thought to stem from a combination of biological and environmental factors. Not surprisingly, there is a high degree of comorbid mental health conditions in individuals with BPD. One study of males with BPD on probation found an average of 6.2 psychiatric diagnoses in these individuals. In terms of genetics, BPD is approximately 5 times more common in individuals who have a first-degree relative with the condition when compared to the general population. In addition, twin studies have shown a higher concordance rate of BPD in monozygotic (identical) versus dizygotic (fraternal) twins. Both functional and structural neuroimaging studies have found abnormalities in frontal and limbic areas including the prefrontal and orbital cortices, amygdala, and anterior cingulate cortex. Abnormalities have also been noted within the brain's serotonin system.

In terms of environmental factors, a history of abuse is common in individuals with BPD. Family

dynamics are frequently dysfunctional, and it is not uncommon for an individual with BPD to have experienced a history of early-onset and prolonged abuse. This has prompted some researchers to note the similarities between individuals with BPD and what is now known as *complex post-traumatic stress disorder*.

Research suggests that the symptoms of BPD may lessen over time and are less stable than previously thought. In a 2003 study conducted by Mary C. Zanarini and colleagues, approximately 68% of individuals diagnosed with BPD met criteria for remission after 6 years. Some risk factors associated with poor outcome include early age of onset, significant instability of affect, and a family history of mental illness.

Treatment of BPD

Treatment of BPD falls into two broad categories: medication and psychotherapy. Medications can help reduce impulsivity, emotional dysregulation, and cognitive distortions (e.g., suspiciousness, paranoia) based on placebo-controlled drug trials examining selective serotonin reuptake inhibitors, mood stabilizing drugs, and antipsychotic drugs. These calming effects can help improve the efficacy of psychotherapy. However, the medications target only symptoms of BPD, and the main treatment for BPD is psychotherapy.

The most widely used form of psychotherapy for BPD is dialectical behavioral therapy (DBT). DBT, developed by Marsha M. Linehan, is a modification of cognitive behavioral therapy. There are four components of DBT: group skills training, individual therapy, phone coaching, and the therapist consultation team, which is a type of support group for DBT therapists to help avoid burnout. DBT teaches individuals four sets of skills: mindfulness, distress tolerance, interpersonal effectiveness, and emotion regulation. Research has found DBT to be an effective treatment for BPD. A 2016 pilot study of an 8-week DBT skills group in an incarcerated male population showed favorable results and lays the groundwork for future studies in correctional settings.

Another commonly used group treatment for BPD is systems training for emotional predictability and problem-solving. Some correctional settings have employed systems training for emotional

predictability and problem-solving group treatment with favorable results, including one study showing that a 20-week treatment program led to improvements in mood and reductions in suicide or self-harm behaviors and disciplinary infractions in both male and female inmates.

BRIEF JAIL MENTAL HEALTH SCREEN

On any given day, 5–15% of men and 20–30% of women jail detainees have a diagnosable serious mental illness, resulting in over 2 million persons with mental disorder admitted to U.S. jails each year. Corrections professionals have a constitutional obligation to provide adequate mental health treatment; thus, they need to immediately triage incoming detainees to determine who is at risk of suicide, who has mental health problems, and who is experiencing typical reactions to

incarceration. To assist jails in meeting their constitutional obligation, researchers developed a valid, easy-to-administer screen for mental health disorders in jails: the Brief Jail Mental Health Screen (BJMHS). This entry discusses the development, validation, and use of the BJMHS.

Development

The BJMHS was developed with funding from the National Institute of Justice to provide jail staff with a short screen to identify detainees with mental health problems who they could refer for additional assessment and appropriate treatment. The goal was to develop a mental health screen that was simple, free, valid, and decisive and could become part of the routine booking procedures in jails.

The BJMHS is derived from the Referral Decision Scale, a clinical screen with high levels of correctly identifying people with serious mental illness, such as schizophrenia and bipolar disorder, and those who do not have serious mental illness. Questions arose, however, that the Referral Decision Scale was not appropriate for corrections populations because it asks about lifetime experiences rather than current symptoms. The BJMHS was specifically designed for use in corrections settings, in particular to identify individuals currently experiencing mental health symptoms and those with a history of psychiatric hospitalization and medication.

The BJMHS includes 8 yes/no items including 6 questions about current symptoms and 2 about medication and hospitalization history. The BJMHS is decisive, leaving no room for ambiguity as to what the staff person administering the screen does with the results. If an individual answers *yes* to 2 of the first 6 items, he or she is referred for further assessment. If the individual endorses a history of either hospitalization or medication for emotional or psychological problems, he or she is referred for assessment. The screen can be administered in 3 min by corrections staff with minimal training, and instructions for the screen and for the results are included on the instrument.

Validation of BJMHS

The BJMHS was validated in 2005 and again in 2007. When validating this screen, it was critical

to know if the screen correctly identified people who needed further mental health assessment and those who did not. It is imperative that corrections staff identify people who need mental health treatment and those who do not to provide a safe environment and to efficiently allocate jail resources.

In the first validation study, the BJMHS was administered to over 10,000 jail detainees in four U.S. jails and identified 11% who needed further assessment. From this group, a stratified random sample of 125 individuals was selected for assessment. From the 89% who did not need further assessment based on their BJMHS outcome, a stratified random sample of 232 detainees was selected. All 357 individuals were administered the Structured Clinical Interview for *DSM-IV* (SCID), a diagnostic clinical tool widely used with corrections populations. Based on the SCID results, the BJMHS correctly identified 74% of men and 62% of women. This means that the BJMHS screen outcome agreed with the longer, clinical assessment in 74 of 100 men and 62 of 100 women.

One group of detainees in the validation study was a concern to researchers: those whose BJMHS said *no mental illness* but whose SCID said *mental illness*. These are referred to as *false negatives*. In effect, these detainees would not be identified at booking as needing a referral to mental health but did, in fact, need more services. In the validation study, the BJMHS incorrectly indicated that 15% men and 35% of women had *no mental health problem* but did when administered the SCID. The opposite outcome—where the screen said *yes* and the assessment said *no*—results in misallocated resources through administering unnecessary assessments, but they were not as concerning as missing detainees who need mental health treatment.

Because of the high proportion of women (35%) whose mental disorder was missed by the BJMHS, a second validation study was conducted in 2007. It was posited that the high number of women with mental disorder not identified using the 8-item BJMHS had symptoms and diagnoses not captured by the instrument. Specifically, it was asserted that the 8 items were not sensitive to anxiety and depression resulting from post-traumatic stress disorder, a common diagnosis

among female detainees. Four questions were added to the BJMHS to determine if a 12-item scale would more correctly match women's BJMHS outcome with their SCID. Using an identical research protocol and three of the same four jails plus one new one, the researchers sought to revalidate the BJMHS-Revised.

The BJMHS-Revised was administered to over 10,000 jail detainees, and 464 individuals were sampled to receive the SCID using the same selection procedures as in the first study. Results from the revalidation study showed that the addition of the 4 items did not improve the accuracy of matching the BJMHS and SCID outcomes for women detainees.

A final inquiry into the validity of the BJMHS was to determine if it is equally accurate across racial groups. Black and Hispanic detainees were slightly less likely than Whites to endorse any of the 6 symptom items, and they were much less likely to report past psychiatric hospitalization or medication.

Use of BJMHS

The BJMHS is used in over 200 jails throughout the United States. It has also been studied in England, Australia, New Zealand, and the Netherlands. While the BJMHS can be administered by corrections staff, the researchers encourage it to be administered by corrections and clinical staff who have interviewing skills and a clear understanding of the purpose of the tool. In addition, it is important to be aware that the BJMHS is better at correctly identifying mental health problems in White males than in males of other races or all women.

BULLYING

Bullying is any unwanted aggressive behavior by another individual or a group of individuals who are not siblings or romantic partners. Bullying involves an observed or perceived imbalance of power that is repeated several times or is likely to be repeated. The power differential can arise from individual characteristics such as strength or from a position in the social group (i.e., status within the group or membership to a specific group). Power imbalances can change over time and vary by situation even if the same individuals are involved.

The repeated nature of bullying means that there have been multiple incidents of aggression over a period of time or there is serious concern that a particular incident has a high probability of being repeated. With each repeated incident, the power differential becomes consolidated. Physical, social, psychological, or educational harm or distress may be inflicted on the target as a consequence of bullying. Therefore, this unhealthy relationship can cause many negative effects in the future.

This entry focuses on descriptors and effects of bullying, followed by controversies in definition, electronic bullying, neurobiology, and intervention efforts.

Bullying Descriptors

Bullying can take several forms, and the content of each form may vary by situations and individual characteristics. There are direct forms of bullying, which occur when actions or words are used to openly hurt another in face-to-face interactions or through written communication. Conversely, indirect forms of bullying are not directly

communicated to the target but are used to damage an individual's reputation or relationships. Physical bullying is a common direct form that involves hitting, kicking, punching, or vandalizing. Verbal bullying is a direct form that occurs when words are used to intimidate or humiliate others through name-calling, mocking, or threatening. Relational bullying is an indirect form that damages relationships by gossiping, excluding, or ignoring.

The content of bullying may vary and includes physical appearance (e.g., weight), sexuality (e.g., unwanted physical contact or rumors about an individual's sexual identity and/or orientation), race or ethnic origin (e.g., racist name-calling or gestures), religious beliefs (e.g., slurs about holidays, clothing, or diet and/or purposeful exclusion from groups), and disability (e.g., based on physical and/or intellectual disability).

Electronic bullying, or cyberbullying, is a relatively new form and is defined as inflicting harm toward another through online communication technology. As with other forms of bullying, it can be direct when messages are openly sent to the target or indirect when insulting messages are posted on a public forum. The defining difference between electronic bullying and the other forms is the use of electronic means and that it can potentially involve a broader audience, has a greater reach, and the ability to permanently exist in cyberspace.

Involvement of Peers

Bullying is social in nature and frequently takes place when individuals come together to form groups. Within any given bullying interaction, there are several roles that individuals may assume, including the bullying perpetrator and victimized youth. Other roles include those that are more overtly involved in the incident such as the reinforcer (e.g., laughing, clapping, or cheering) and the assistant (e.g., helping, joining in). Other children may act as the defender who aids the victimized youth by comforting and supporting them and the outsider who is a passive observer.

Roles tend to be fluid based on the situation; a child may act as a defender in one situation but a reinforcer in another. Associations are often made between social standing and bullying behavior. In longitudinal studies, bullying perpetrators (and

their assistants and reinforcers) score high on popularity but low on likeability. In other words, over time, adolescents high on bullying were less liked by their peers, yet maintained a high position in the classroom hierarchy. Adolescents also tend to like peers with similar levels of bullying and were influenced by their peers, typically when they liked peers high on bullying.

Bullying Demographics

Currently, bullying is a pervasive problem that affects children and youth, as approximately 200 million individuals are being victimized by their peers worldwide. Verbal and social bullying represent the forms with the highest prevalence rates followed by physical bullying. Furthermore, a significant number of youth are victimized online, with prevalence rates between 10% and 35%. Bully victims, children who are both victimized and bully others, represent between 2% and 4% of all students and between 30% and 50% of the bullying perpetration group. Notably, occasional victimization has decreased from 33.5% in 2001–2002 to 29.2% in 2009–2010, which was seen in 11 of 33 countries. Decreases are also reported across Europe and North America in chronic victimization from 12.7% in 2001–2002 to 11.3% in 2009–2010. Rates of bullying and victimization can vary by age and sex.

Bullying and victimization increase steadily during childhood, reaching a peak in middle adolescence (i.e., 14–15 years old), as youth transition to high school, followed by a decline in the number of reported incidents. Younger children tend to favor direct forms such as pushing or name-calling; however, with age, individuals tend to favor more indirect forms of bullying such as social exclusion. Physical bullying declines with age, while verbal, social, and electronic bullying tend to increase between the ages of 11 and 15 years. Boys are more likely to use physical bullying. Girls tend to begin using social bullying earlier than boys, but both sexes reach about the same level of social bullying by middle adolescence. Both sexes are also equally likely to use verbal and electronic tactics especially in middle adolescence. Finally, boys are prone to bully other boys rather than girls and boys also disclose higher levels of bullying.

Effects of Bullying

There is a wide range of harmful effects associated with bullying perpetration and victimization. Perpetrators of bullying experience somatic symptoms such as headaches and bed-wetting as well as behavioral problems such as attention-deficit disorder and oppositional conduct disorder. They are also at risk of long-term mental health-related issues such as depressive symptoms, suicidal ideation, alcohol abuse, and substance use. Importantly, perpetrators are at a higher risk of delinquency and crime in adult years as well as prolonged social problems. They are more likely to have a positive attitude toward physical aggression and experience more externalizing and antisocial problems in adulthood. By age 30, perpetrators of bullying are more likely to have had criminal convictions and traffic violations. They are also more likely to demonstrate physical aggression toward their spouse and physical punishment on their children.

That said, it is the victimized youth who face greater negative effects from being victimized. Victimized youth experience more somatic symptoms such as headaches, colds, sleeping difficulties, stomach pains, and low appetite. They also experience greater levels of internalizing disorders such as anxiety and depression, especially for girls, as well as loneliness, withdrawal, and in extreme circumstances suicidal ideation. Individuals who are victimized may perceive less social support and have poor self-esteem and a fear of school. That is, they feel unsafe, unhappy, and, in certain cases, may drop out of school to avoid the pain. The prolonged and severe stress associated with victimization can be never-ending, as individuals are able to relive the pain. This cycle is associated with a clinical range of post-traumatic stress disorder in 28% of boys and 40% of girls in Grades 8 and 9.

Despite the detrimental effects of bullying, laws are slow to change. In Canada, bullying is considered illegal if it involves death threats, severe bodily harm, assault, criminal harassment, or distribution of intimate images without consent. The importance of bullying prevention has become apparent in Canada and the United States. In Canada, schools are mandated at the provincial level to have an intervention program. Schools are also required to evaluate whichever program they have chosen to implement, as

bullying may be interpreted as a violation of the Charter of Rights and Freedoms. In the United States, most bullying legislation is determined at the state level and all states have passed school antibullying legislation.

Major Issues

Several controversies have emerged in the study of bullying. These include definition problems, traditional versus electronic bullying, neurobiology, and intervention efforts.

Researchers fail to work under a mutual definition of traditional and electronic bullying. There is debate regarding whether intention and repetition should remain in the definition. The lack of consensus means that many researchers measure aggression instead of bullying because they fail to consider the repetitive aspects of the construct. A similar debate applies to electronic bullying definitions, leading to a lack of valid and reliable measurement. If academics cannot agree on a definition, there will likely be similar problems when it comes to bullying prevention and intervention efforts.

In both traditional and electronic bullying, the goal is the same: to harm, harass, embarrass, or socially exclude another individual. Those who are victimized in person also tend to be victimized online. The negative outcomes of electronic bullying are similar to those of traditional bullying; however, electronic devices add another layer to the relationship between the perpetrator and victimized youth. The bullying relationship becomes more complex due to potential anonymity (i.e., use of a pseudonym), the larger and broader audience who may witness the bullying or have access to it online, lack of supervision and consequently less likelihood adult intervention (i.e., no consequences for their behavior), and increased accessibility to the target. Thus, while the dynamics involved in electronic bullying and traditional bullying are similar, the context of social media add features that heighten the negative effects. There is some disagreement regarding whether electronic bullying is fundamentally different from traditional bullying or whether it just happens in a different medium.

A newly emerging field in the bullying literature is the neurological processes associated with both bullying and victimization. To understand

how peer victimization may contribute to poor mental health, a growing body of research has begun to explore the neural correlates of peer victimization. Children who have been victimized show blunted hypothalamic–pituitary–adrenal axis activation in response to stress, thus producing less cortisol, which is a common experience in people with prolonged and severe stress. Similarly, peer victimization has been shown to exhibit reduced cardiovascular and galvanic skin response to simulated social exclusion. In studies using functional magnetic resonance imaging to explore brain function, social exclusion (a form of relational peer victimization) has been shown to elicit activity in multiple regions including the dorsal anterior cingulate cortex, insular cortex, and prefrontal cortex. The dorsal anterior cingulate cortex is associated with processing the unpleasantness of physical pain, and the insula is related to processing visceral sensations. Furthermore, activation in the right ventral prefrontal cortex is implicated in the regulation of physical pain. These findings suggest that experiences of bullying and victimization may be associated with changes in biological processes that may be an underlying mechanism explaining the link between victimization and poor health. This relatively new area of research may increase current understanding of the long-term effects of involvement in bullying.

Bullying prevention programs attempt to reduce the number of incidents; however, program effectiveness lags behind prevention research. Most programs produce little change, and some programs may produce negative effects, especially those that focus on deviant peers. At best, prevention programs produce modest effects and are more likely to influence attitudes and knowledge rather than behaviors. The limited effectiveness means that the research community needs to identify critical elements of program success in bullying prevention programs. Successful bullying intervention strategies aim to target the entire school population (a whole school approach) that addresses wider systemic factors. Research has indicated that interventions should be evidence based (i.e., theoretically and empirically driven). Furthermore, program intensity and duration are linked to effectiveness. Programs may be ineffective because schools experience difficulty implementing and maintaining such programs. There is

often a lack of training and manuals for program delivery, contributing to program drift, and schools often struggle with having adequate funding for implementation. Bullying prevention programs require a balance between fidelity and adaptability to be successful. Finally, program maintenance often requires that the program become embedded in the school's culture and align with other initiatives. More research is required to facilitate the development and implementation of effective bullying prevention programs.

BURGLARY

Sir Edward Coke (1552–1634) was appointed Chief Justice of England's Court of Common Pleas in 1606 and had a varied judicial and political

career. In his four-volume *Institutes of Laws of England*, he defined burglary essentially as breaking and entering a private dwelling at night with the intent to commit a crime inside (usually theft but may include violence if an occupant discovers the burglar). Although some of the details have changed over the centuries, *burglary* retains Coke's classic defining features. For example, *unauthorized entry* into a building or structure remains salient, as does the *intent to commit a crime within*, which is usually theft. However, time of entry, type of entry, and site of entry, as well as other details, have broadened, depending on the judicial territory. First, time of entry extends from nighttime to daytime. Second, the burglar need not literally break anything to enter but may simply walk, reach, or crawl inside through a doorway, window, or any other access point. Third, in addition to one's private dwelling, burglary extends to almost any structure that shelters people, animals, or property, such as a garage, mobile home, motel or hotel room, office building, barn, apartment, railroad car, boat docked at a marina, or retail store (during closing hours). In the United States, depending on the state and the specifics of the crime, burglary may be prosecuted as either a misdemeanor or a felony. For example, it may be a felony if the burglar possesses a weapon, steals property valued above a particular dollar threshold, or assaults an occupant.

Since the year 2000, roughly 3 million or more burglaries occur each year in the United States. The chances of a residence being burglarized in a given year is about one in 50. In the majority of residential burglaries, a door or window is forced open to gain entry. Most residential burglaries go unsolved, with arrests in only about 10% of the cases and convictions in only about 3% of the cases. The best predictor of an arrest is the presence of a witness (usually an unexpected occupant). The average dollar value of property stolen per burglary is about US\$600. Although cash and firearms are of high premium, they are obtained in less than 10% of the burglaries. The most common items stolen are jewelry, watches, purses, wallets, credit cards, power tools, silverware, guns, and portable electronic equipment such as laptop computers, smartphones, digital cameras, and video and game players. This entry reviews the common characteristics associated with burglaries and those who engage in this behavior.

The Burglar

Most residential burglars are males. Although their ages range from the early teens to middle age, the majority are between 15 and 25 years. The young or novice burglar must acquire skills, which include selecting targets that have something worth stealing, breaking and entering, searching for items of value once inside, escaping without detection, and disposing of the stolen property. These skills are usually learned from older more experienced burglars, often relatives.

Although a small percentage of burglars may be defined as *professionals*, making the bulk of their income from burglary, the vast majority commit burglary as one of many crimes and *hustles* that sustain their criminal livelihood. Some researchers refer to these individuals as *opportunists*. They are opportunists in the sense that they follow the path of least resistance, often responding to immediately presented chance opportunities while driving, riding a bike, or walking. Their targets are generally within a few miles of their own residence, and in approximately 65% of residential burglaries, the burglar is acquainted with the occupant.

Opportunists may also seek chance opportunities in the sense that they actively search for situations in which monetary gains may be obtained through driving or other transportation means and through informants or *insiders*. Their targets tend to be in areas where their routine activities occur and along their day-to-day travel routes.

Burglars tend to live day to day, and considerations of next week or next month do not enter their stream of consciousness. Their here-and-now orientation, coupled with their need to keep up a party-style appearance to others, is incompatible with securing a full-time job. Their predilection for drug abuse also inhibits gainful employment. There is better than a 75% chance that the burglar is abusing or addicted to an illicit drug such as heroin and other narcotics (e.g., oxycodone), methamphetamines, cocaine, and marijuana or licit drugs such as alcohol. Unlike a legitimate occupation whereby monetary rewards are delayed, the rewards for burglary are numerous and immediate. Many will use the proceeds from their burglaries to purchase more drugs.

Most burglaries are successful in that the burglar is rarely caught. The burglar knows that the

probability of being arrested is low, and that convictions are slim. They also know that punishment is relatively light if convicted, especially for the first offence if unarmed. Consequently, in approximately 75% of household burglaries, the burglar does not carry a firearm. Unarmed, there is less fear of punishment. The *fear* that exits does not come from apprehension and punishment but rather from the actual execution of a burglary elicited by the *potential* of an unexpected occupant. In over 25% of burglaries, an occupant is present. Although the majority of burglars are not prone to violence, about one third of the cases where the burglar encounters an occupant result in violence (usually simple assault).

Motivation for Burglary

The immediate motivator driving burglary is the acquisition of money. The goal is to acquire property and convert it to cash and thereby support *partying* activities, *keep appearances*, and purchase drugs (including alcohol). Secondary motivators often include the thrill and excitement of the burglary event and, sometimes, getting revenge for a prior slight. Younger burglars tend to be get more excitement thrills than older, more experienced burglars. Pangs of conscience or feelings of guilt are virtually nonexistent, regardless of age.

The excitement begins with the anticipation of entering a residence. Once inside, the excitatory emotion is what many burglars describe as an *adrenaline rush*, a very pleasurable emotion. Searching and choosing items to carry away sustains the exhilaration. The excitatory emotion co-occurs with the fear of encountering an occupant and detection. Exiting the residence and escaping undetected eliminates this fear and serves as another pleasurable emotion in the burglary sequence. To keep excitement in check and to reduce fear, many burglars prefer to be under the influence of a drug while executing their burglaries, claiming they are better burglars. They report needing to *be steady*, and that a moderate dose of their preferred drug enables them to be calmer, less fearful, more decisive, and faster.

Target Site Selection

Burglars work alone or with cooffenders during periods when residences and businesses are

unguarded. The majority of residential burglaries are committed in the daytime (6 a.m. to 6 p.m.), with the most common interval between about 10 a.m. and 3 p.m.; this is the time residents are likely to be working or seen leaving, perhaps to shop or drop-off and pickup children. Similarly, office and retail stores are more likely to be burglarized at night because workers are absent. Once the decision is made to commit a burglary, the burglar employs a basic three-step decision strategy acquired through mentoring, modeling, and experience.

The first step in the decision strategy is an assessment of target sites for some minimal potential monetary gain. Most burglars can rapidly estimate potential gain based simply on external appearances of the residences, including the general affluence of the neighborhood. Larger and better maintained houses are judged to have more property worth stealing. Houses with newer, more expensive automobiles associated with them are judged to have greater expectation of gain. However, higher income households experience lower rates of burglary. Approximately 45% of household burglaries occur in neighborhoods where the annual household income is less than US\$15,000. This is likely because residential burglars, in addition to being opportunists and without gainful full-time employment, live in lower income housing themselves and are more likely to burglarize dwellings in close proximity to their own. They're also apt to know their victims and thus have information about what's inside of value.

The more experienced burglars often work with *insiders* who have access to more gainful targets and who are willing to provide the burglar with information about valuables and the comings and goings of the occupants. Sometimes, maids, gardeners, and service workers (e.g., appliance repair, carpet cleaning, pizza delivery, lawn maintenance, plumbing, carpentry, painters) reveal such information in casual conversation without intending to assist the burglar. The burglar needs to *fit in* to the neighborhood. It is easier to fit into more affluent neighborhoods when one poses as, or works as, a service worker. Many burglars will occasionally pose as a salesman or work as painters, yard keepers, or carpenters' helpers so they can learn habits of the occupants and, equally important, to learn about the neighbors. The burglar may then return in a couple of weeks and break into one of the homes in the neighborhood.

More burglaries occur in the summer months because there are generally more service-related activities and commonly more routine family activities outside the home, thus the burglar is less apt to stand out. On one hand, residences near schools, businesses, and main thoroughfares, and more access routes are more vulnerable to burglary. On the other hand, residences that are off the route of a burglar's routine activities, and where the burglar may not fit in as well, are less susceptible to burglary—that is, residences in gated or walled communities, or otherwise restricted access (e.g., apartment buildings), and residences on cul-de-sacs and streets with fewer intersections.

The second and most critical step the burglar takes to arrive at a decision to break into a residence is to determine whether anyone is inside the home. The ideal target is one that is unoccupied and where no one else may see them—and where there are no loud barking dogs to attract attention. If someone is inside the home, then a potential burglary event is often immediately aborted. The burglar may return later or search for a new target site. The burglar also needs to determine whether a neighbor or anyone passing by may see them. The presence of a neighbor, passersby, a loud barking dog, an alarm system, or secure deadbolt hardware can serve as deterrents and displace the burglary event elsewhere. In general, burglars prefer targets that do not have alarm systems.

The third step in the decision-making process is to determine the difficulty of actually breaking into the target site. Most burglars are not particularly skilled and use brute force to gain entry, either through a door or window, preferably in the rear where one is out of sight. Entering through unlocked doors and windows is not uncommon. Picking locks or disarming alarm systems is beyond the repertoire of the vast majority of burglars.

Once inside, the burglar must search and locate property worth stealing. Few burglars make a careful search of the dwelling. They need to be in and out as quickly as possible. Most want to be out within 5 min, knowing that police response time is generally greater than 5 min if reported. Master bedrooms and baths, closets, and drawers of all kinds are good places to find valuables. Most will also inspect medicine cabinets seeking prescription medications. Burglars also frequently look in the refrigerator and

freezer for hidden cash. Leaving the burglary site and transporting these items is risky, especially for burglars who walk or ride a bicycle to the crime site. Consequently, burglars anticipate their getaway before they enter and focus on stealth when leaving, often planning two avenues of escape.

The general three-step process involved in a decision to burglary a home or business appears to indicate a rational process whereby the burglar evaluates dwellings prior to burglary. However, burglars are often under the influence of drugs and may act with little forethought when they spot an opportunity. When opportunity arises, the burglar has to act fast. Most often, they are lucky as opposed to being rational planners and complete the burglary without arrest.

CAREER PATHS IN CRIMINAL JUSTICE

Criminal justice as a career path offers a wide array of positions and subspecialties, each supporting the goals of public safety and upholding the principles of government. This entry examines and delineates the roles of various criminal justice professionals in judicial, law enforcement, and correctional domains, highlighting auxiliary responsibilities and general knowledge, skill, and ability requirements for each role.

Judicial Domain

The judicial system comprises numerous positions within the criminal justice system, including judges, criminal prosecutors, correctional officers, and probation and parole officers. Integral to the criminal justice system is the tenet that justice is not only sought but fairly applied.

Judges are a crucial part of the system, often as one of the first individuals in the criminal justice system a person charged with a crime encounters, such as during the arraignment process (when the person charged enters a plea of guilty or not guilty). Generally, district judges must possess a law degree and have experience as a prosecutor. Other duties of judges involve signing search warrants and handing down sentences for those found guilty or exonerating an individual upon good cause. Alternatively, a judge may order probation if an individual's crime is considered minor.

Judges also oversee the judicial process as it relates to the prosecution of criminal offenses. Anyone interested in prosecuting criminal cases on behalf of the state or local government must obtain a law degree and be licensed to practice law within a specific jurisdiction.

Oftentimes an offender will receive punishment in the form of incarceration at a correctional facility such as a jail or a prison. Correctional officers are tasked with maintaining security in these facilities. An individual may prepare for a career as a correctional officer by taking specific corrections courses, and many law enforcement agencies require rookie officers to serve a year as correctional officers before assigning them to street patrol.

Probation, an alternative to serving jail or prison time for minor offenses, is overseen by a probation officer. This person supervises the conduct of an individual granted probation by a judge. A probation officer must generally possess some college experience and be able to manage multiple, diverse caseloads.

Parole officers monitor the activity of correctional inmates after they have been released into society on parole. Such monitoring serves as a measure of public safety and recidivism reduction. In accordance with this responsibility, parole officers can implement a range of actions, including unannounced home visits and mandatory urinalyses. Many jurisdictions require parole officers to have a bachelor's degree in some field related to criminal justice.

Law Enforcement Domain

Patrol

Many police officers begin their careers in a highway or a street patrol. In fact, most police agencies require several years of patrol experience before allowing advancement to other specialized areas of law enforcement. In a broad context, the primary goals of a police patrol are (a) to deter crime by incorporating the visible presence of a marked police unit, (b) to reduce the occurrence of vehicular accidents, and (c) to interdict illicit activities. The community-oriented policing model revolutionized approaches to patrol efforts by integrating strategic-oriented policing, neighborhood-oriented policing, and problem-solving policing. Because criminal activity and vehicular accidents are not uncommon phenomena, occurring day and night, patrol officers work varying schedules in order to meet the demands of 24-hour coverage.

Numerous factors play into the responsibilities of a patrol officer, including agency size and the geographic area served. For example, local police departments generally focus on urban-related traffic violations and service calls by concerned citizens and complainants of criminal activity. Many of the larger police departments in the United States have the ability to direct patrol activities toward specific areas, such as speed enforcement, accident investigation, and highway narcotics interdiction. Each state utilizes a highway patrol to enforce traffic laws on state and interstate highways. These officers are also highly trained in the areas of accident investigation and criminal interdiction.

Technological advances have changed how patrol officers and other law enforcement officers carry out their duties. Computer tablets have replaced the pen, and analog radio systems now comprise digital units. Advancements in radar technology have enhanced speed enforcement activities. Many of these changes were implemented in the aftermath of the events of September 11, 2001, and have changed the landscape of police work and intelligence systems. Fusion centers have been created in an effort to provide a type of proactive intelligence platform whereby information can be shared among various local, state, and federal agencies. In contrast to attending shift roll

call, patrol officers are now equipped with robust, in-car computer networks connecting them to critical incident data in real time. Having this technology allows officers to begin their shift in their patrol unit, rather than at roll call, which can also help police agencies effectively manage resources and costs.

Aviation

Many mid-size and large police agencies employ aviation assets as a mechanism of public safety. Typically, aviation officers can choose to focus on either fixed wing (airplane) or rotor wing (helicopter). While both can cover large geographic areas, fixed wing aviation assets may be used to transport prisoners and conduct aerial reconnaissance, whereas rotor wing aviation is generally used to survey areas to identify such criminal activity as growing marijuana crops, to transport officers from one location to the next, and to carry out manhunt operations. Some officers seek to qualify as a flight tactical officer whose job is to sit next to the pilot and make observations of criminal activity.

Officers choosing the aviation career path are generally more tenured but do not necessarily have to be of advanced rank for consideration. It is not uncommon for agencies to require prior licensure as a pilot.

Federal Law Enforcement Careers

While the focus in this entry so far has been on local law enforcement, there are also many potential career paths within federal law enforcement. With over 70 federal law enforcement agencies employing investigators, often called *special agents*, careers in federal law enforcement can take many paths with a variety of agencies, each with its own mission. Most agencies have exclusive enforcement delineations, while others have broad authorities. For example, the mission of the Drug Enforcement Administration (DEA) is to enforce U.S. laws and regulations regarding controlled substances. The mission of the Federal Bureau of Investigation is to protect and defend the United States against terrorist and foreign intelligence threats, to uphold and enforce the criminal laws of the United States, and to provide

leadership and criminal justice services to federal, state, municipal, and international agencies and partners.

The hiring process for federal law enforcement positions is competitive. The stronger the applicant's education, experience, and specializations are, the more likely the candidate is of obtaining the first step in the hiring process. The list of federal law enforcement opportunities available to individuals with diverse educational and professional backgrounds is ever expanding. Often, the decision-makers of agencies are searching for individuals who hold degrees in fields beyond criminal justice. Psychology, law, forensic accounting, political science, emergency management, foreign language, computer technology, and homeland security are some desirable educational backgrounds.

As national security threats expand, so does the need for individuals with additional qualifications, such as a specialty in cybersecurity. Each agency has distinctive training programs and prefers candidates who bring specialized knowledge and skills to fulfill positions that contribute to the agency's mission. Once hired, the individual will sign a mobility agreement and attend an academy for training. Because relocation and travel are common to these positions, those who prefer not to relocate may wish to pursue a career in a local or state law enforcement agency.

Depending on the agency's mission, the job duties of special agents vary, although in a basic sense they gather evidence through informants, undercover operations, surveillance methods, search warrants, interviews, and interrogation. Covert surveillance may include visual observation, wiretaps, and tracking and electronic methods obtained by a written permission from a court. Agents are required to write a detailed affidavit establishing probable cause when requesting court permission to electronically intercept evidence. Agents must also keep copious notes and reports of surveillance findings. Depending on the court-authorized search warrant issued, agents may examine personal, financial, and business records as well as electronic documents for evidence in furtherance of an investigation. Agents also serve arrest warrants, prepare for court proceedings, and testify on the evidence presented.

In addition to special agents, federal law enforcement agencies have a number of support positions that carry out important roles. These include polygraph operators, training coordinators, firearms instructors, confidential informant coordinators, recruiters, victim witness coordinators, critical incident responders, internal affairs investigators, and public information officers. These positions are usually available to experienced agents or those with specialized training.

Alternative Careers in Federal Law Enforcement

In addition to special agents and support positions, federal law enforcement agencies offer career opportunities in a variety of disciplines. Within each agency, specialized positions are utilized to further the agency's purpose. This section describes a few diverse opportunities within DEA to provide examples of career paths within a single-mission federal law enforcement agency.

DEA chemists analyze substances seized by law enforcement to determine whether they are illegal or controlled substances, and they may testify in court, usually for the prosecution, regarding the composition of such substances. DEA intelligence analysts provide information to assist with investigations, help with trial preparation, and deliver reports and statistics to supervisors when requested. Diversion investigators perform investigations into operations related to pharmaceutical drugs and drug-manufacturing chemicals. These types of supporting careers may be often overlooked when one is seeking a career in criminal justice, but they can offer exciting and rewarding opportunities within the criminal justice field.

Corrections Domain

In addition to the correctional positions that fall into the judicial domain (i.e., probation officers, corrections, and parole officers), there are various other administrative and support positions within the correctional system. The warden is responsible for administrative oversight, which includes the day-to-day operation of matters such as budgeting, policy development, personnel management, and goals that support offender treatment.

Generally, a warden must have an advanced degree in public policy and have an extensive experience in executive management.

In addition to the warden, other administrators are needed to ensure that policies that support the mission of justice are effectively carried out. Administrator jobs are typically obtained by first serving several years as a manager within the facility. However, an individual may be able to secure a jail or a prison administrator job by having an advanced degree in business or public administration, coupled with prior management experience.

Because the ultimate goal of incarceration is rehabilitation, mental health professionals are employed to care for and treat offenders who have psychological disorders. In addition, medical staff are employed in order to address ailments associated with normal life-span development as well as those resulting from within the institution such as assaults or communicable diseases. Finally, each inmate is assigned a case worker, who closely monitors the inmate's status and reports directly to a parole board regarding the status of the inmate's progress.

The precise execution of each of the aforementioned roles is needed to successfully implement policies dedicated to offender rehabilitation and lessen recidivism.

Final Thoughts

Together, the judicial, correctional, and law enforcement components of the justice system carry out justice and, when carried out efficiently, positively impact public safety. The broad role of the criminal justice professional, then, is to ensure that the goals of justice are served within the parameters of government.

CENTRAL INTELLIGENCE AGENCY

The Central Intelligence Agency (CIA) is the main foreign intelligence and counterintelligence agency in the United States. It is one of the 16 agencies of the U.S. Intelligence Community, functioning under the umbrella of the Director of National Intelligence. The CIA is an independent, civilian agency, which collects, processes, and analyzes national security information throughout the world, mainly via human intelligence.

The legal framework for the organization and functioning of the CIA resides in the National Security Act of 1947, Executive Order 12333 of December 4, 1981, the Intelligence Reform and Terrorism Prevention Act of 2004, as well as additional laws, rules, and regulations. The CIA's headquarters is named the George Bush Center for Intelligence and is located in Langley, VA. Democratic civilian control and oversight of the CIA involve the executive branch direction and guidance, legislative scrutiny through two congressional select committees, internal control mechanisms, judicial review, as well as informal oversight by the media and civil society.

This entry reviews the historical background, mission, and organization of the CIA and then offers both accolades and criticisms.

Historical Background of the CIA

The United States has conducted intelligence activities since the times of the Revolutionary War (1775–1783), but only since World War II has the United States carried out such activities systematically. After the United States entered World War II, it established the Office of Strategic Services (OSS)

in June 1942, to provide intelligence to the Joint Chiefs of Staff and carry out special clandestine operations that were not conducted by other government institutions. The OSS did not, however, have global focus and missions. Despite this, the OSS's intelligence was vital to the preparation and development of various military operations conducted during the war. Notwithstanding, President Harry S. Truman regarded the continuation of the OSS activities impractical after the war; therefore, he closed the OSS in October 1945 and reassigned most OSS functions to the Departments of War and State. During this period, the president received various proposals to create a federal civilian intelligence agency, responsible for the national intelligence collection and for the coordination of the overall U.S. intelligence endeavors. However, he did not act upon any of these proposals in the immediate postwar period, partly because he tended to support the separation of roles and responsibilities among various agencies and, partly, because of opposition from the Armed Forces and the Federal Bureau of Investigation (FBI), which considered the creation of a civilian intelligence agency a threat to their activities, authority, and influence.

Eventually, President Truman became increasingly aware of the need for a civilian intelligence organization, due to the lack of coordination and sharing among the existing military and security agencies on the one hand, and the existing Cold War security context, which called for accurate and timely intelligence about the Soviet Bloc, on the other. In January 1946, President Truman created the Central Intelligence Group to ensure the coordination of intelligence collected by existing organizations, operating under the umbrella of a National Intelligence Authority, composed of the president, the secretary of state, the secretary of war, and navy departments. Central Intelligence Group was the first peacetime intelligence agency in the United States. Central Intelligence Group and National Intelligence Authority functioned for approximately 2 years.

In 1947, President Truman signed the National Security Act of 1947, which created the CIA and the National Security Council. In line with the law, the CIA was responsible for U.S. intelligence activities and coordinating, assessing, and disseminating all intelligence related to U.S. national

security, as directed by the National Security Council, tasked to operate on foreign soil, and forbidden from conducting intelligence and counterintelligence activities inside the United States. Since its creation and until the end of the Cold War in the early 1990s, the CIA's main focus was to curb the propagation of the Communist Bloc and ideology globally. Toward this end, the CIA routinely carried out clandestine operations. The present-day mission of the agency is to avert security threats and advance U.S. national security objectives, by gathering relevant intelligence, generating all-source analysis, carrying covert operations as directed by the president, and protecting U.S. secrets. The CIA's number of employees and budget are classified, as stipulated by the Central Intelligence Agency Act of 1949.

The 1947 Act created the position of the Director of Central Intelligence, who was the head of the CIA, the coordinator of the U.S. Intelligence Community, and the principal advisor to the president for national security intelligence. This position was terminated on December 17, 2004, when President George W. Bush signed the Intelligence Reform and Terrorism Prevention Act, in response to criticism of the poor performance of the U.S. Intelligence Community prior to the terrorist attacks on September 11, 2001, as well of the U.S. Intelligence Community's inaccurate analysis on Iraq's alleged possession of weapons of mass destruction prior to the Iraq War. The Intelligence Reform and Terrorism Prevention Act established the positions of the Director of the Central Intelligence Agency (D/CIA) and Director of National Intelligence, replacing the Director of Central Intelligence.

Mission, Leadership, Structure, and Organization

Nowadays, the CIA's main role is to provide senior policy-makers in the United States—the president, his cabinet, and members of the U.S. Congress—with intelligence on a wide spectrum of national security issues, collected mainly from human sources, as well as via other appropriate ways and means, such as open sources, cyber domain, and geospatial images. The CIA may also carry out counterintelligence activities.

The CIA is the only agency authorized by law to conduct covert operations, as directed by the

U.S. president, unless the president nominates a different agency to do so. Since 1975, when President Gerald R. Ford issued an executive order that banned assassination by the CIA, the CIA is forbidden from carrying out assassination operations. In addition, since 1989, when President Ronald Reagan signed Executive Order 12333, the CIA is forbidden from collecting foreign intelligence on the domestic activities of U.S. citizens. Unlike the FBI, which is a federal domestic law enforcement agency, the CIA does not possess any law enforcement role; therefore, it has no power of subpoena, mandate to arrest anyone, or authority to enforce any laws. It, however, collaborates with the FBI directly and cooperates with the FBI and other law enforcement agencies under the operational framework of fusion centers, as well as under the framework of the NCTS. Nevertheless, the CIA's involvement in criminal psychology is rather limited to funding psychological projects conducted between the mid-1950s and the early 1970s—such as MKUltra, which involved experiments on human subjects, including drug testing—as well as engaging the agency's psychologists in developing the CIA-enhanced interrogation program.

The CIA's intelligence and counterintelligence gathering within the United States is, therefore, limited and occurs in coordination with the FBI. The CIA is legally prohibited from conducting electronic surveillance inside the United States, unless it is carrying out training, testing, or countermeasures to hostile electronic surveillance. The agency is also forbidden by law to conduct unconsented physical searches within the United States, except for specific searches of legally obtained personal property of foreign citizens. The CIA is legally prohibited from carrying out physical surveillance of U.S. citizens within the United States, unless the monitored persons are current or previous CIA employees, current or previous intelligence element contractors (or their current or former personnel), applicants for any CIA employment or contracting, or those working for a nonintelligence element of a military service. The agency is also legally banned from conducting physical surveillance on U.S. citizens abroad, unless there is no alternate avenue for the CIA to acquire critical national security information.

The CIA is headed by the D/CIA, who is nominated by the president and confirmed by the

senate. The D/CIA reports to the Director of National Intelligence and also relates with the White House and the Congress. The D/CIA runs the agency's routine operations, personnel, and budget and serves as the National Human Source Intelligence Manager. The D/CIA is assisted by 12 deputies and departmental directors as follows: the Deputy D/CIA, the Executive D/CIA, the Deputy D/CIA for Analysis, the Deputy D/CIA for Operations, the Deputy D/CIA for Science & Technology, the Deputy D/CIA for Support, the Deputy D/CIA for Digital Innovation, the Associate D/CIA for Talent, the Director of the Center for the Study of Intelligence, the Director of Public Affairs, the General Counsel, and the Inspector General.

The CIA encompasses five distinct components that carry out the intelligence cycle: the Directorate of Operations, the Directorate of Analysis, the Directorate of Science and Technology, the Directorate of Support, and the Directorate of Digital Innovation. The Directorate of Operations is tasked with the clandestine collection of foreign intelligence, primarily via human intelligence, as well as covert operations. It is also the national authority for coordination, deconfliction, and assessment of secret human intelligence activities conducted throughout the Intelligence Community. Directorate of Operations personnel live and work abroad.

The Directorate of Analysis is tasked with the analysis of all-source intelligence, as well as with producing reports and briefings on relevant foreign intelligence developments and threats (e.g., the President's Daily Brief and the World Intelligence Review), which are further disseminated to intelligence consumers.

The Directorate of Science and Technology is tasked with finding innovative scientific, engineering, and technical solutions to the most pressing intelligence-related problems. Throughout the years, several such innovations have been taken over by other U.S. intelligence agencies and/or even the military.

The Directorate of Support is tasked with providing various types of support to the CIA, such as continuous facilities, financial, medical, logistic, and security-related support.

The Directorate of Digital Innovation is tasked with ensuring the boosting of the CIA's innovation efforts with groundbreaking digital and cyber capabilities.

The D/CIA is supported by additional staff, specialized in acquisitions, communications, public relations, human resources, protocol, congressional matters, legal issues, and internal control.

The CIA also includes 10 mission centers that are not attached to any particular directorate, but focus on regional (Africa, East Asia/Pacific, Europe/Eurasia, Near East, South/Central Asia, and Western Hemisphere) or functional (global, counterintelligence, counterterrorism, and weapons and counterproliferation) issues. The CIA publishes various unclassified documents, papers, and professional journals, such as *The World Factbook*, the *Studies in Intelligence* journal, and the unclassified *Kent Center Occasional Papers*.

Accolades and Criticism

Until the early 1960s, the CIA received many accolades, due to its important role in curbing the spread of Communist ideology. One example involves the agency's discovery of Soviet nuclear missiles in Cuba in 1962. From the 1960s to the early 2000s, the agency was involved in various controversial activities and failures to anticipate several national security threats and developments. Relevant examples include failed covert actions, such as the Bay of Pigs operation in 1961 aimed at overthrowing Cuban Dictator Fidel Castro; involvement in arms smuggling operations, such as the Iran–Contra Affair in the 1980s; and failure to anticipate and thwart the terrorist attacks of September 11, 2001. Since September 11, 2001, the CIA has played a key role in the fight against terrorism, including playing a central part in the capture and death of Al-Qaeda leader Osama bin Laden. Nevertheless, some CIA activities, such as the use of enhanced interrogation techniques and the detention of foreign nationals, continue to be criticized and are the sources of ongoing controversy.

CHILD MALTREATMENT AND PSYCHOLOGICAL DEVELOPMENT

Child maltreatment refers to acts of commission or omission of a child under the age of 18 years by a parent, a caregiver, or a person in a custodial role that results in harm, potential for harm, or threat of harm to a child. It is a significant public health and societal concern that has numerous negative consequences for the development of a child. These consequences range from acute and severe (e.g., traumatic brain injury, death) to long-term negative outcomes such as mental health problems and behavioral difficulties (e.g., post-traumatic stress disorder, substance abuse, increased risk for suicide). Of the various areas of child development that are impacted (e.g., impaired brain development), child maltreatment has a profound and long-term impact on psychological development.

Types of Child Maltreatment

There are four common types of child maltreatment: neglect, physical abuse, sexual abuse, and emotional abuse. *Neglect* is the failure to meet a child's basic physical and emotional needs (e.g., access to medical care, education, clothing, food, and housing). *Physical abuse* is the use of physical force (e.g., hitting, kicking, shaking) against a child. *Sexual abuse* involves inducing or coercing a child to engage in sexual acts (e.g., fondling, penetration, exposing them to other sexual activities). *Emotional abuse* involves behaviors (e.g., name calling, cursing, rejection, shaming, withholding love, threatening) that negatively impact a child's sense of self-worth or emotional well-being.

Statistics

In 2015, there were approximately 700,000 substantiated cases of child victims of abuse and neglect in the United States, with 1,670 resulting in fatalities. Neglect was the most common, comprising approximately 75% of reported cases, while physical abuse accounted for 17% of cases and sexual abuse accounted for 8% of all substantiated cases. Parents, whether it be the mother acting alone, father acting alone, or both acting together, accounted for 92% of perpetrators in reported cases. Younger children are the most vulnerable to maltreatment with 25% of victims being 3 years or younger. Overall, the percentage of victims by gender appear to be fairly similar between girls (51%) and boys (49%), but boys experience higher rates of child abuse and neglect when 5 years and younger, and girls experience higher rates of child abuse and neglect between the ages of 6 and 17 years. Relatedly, sexual victimization increases for girls in adolescence, but not for boys. Overall, approximately one in 20 boys and one in 5 girls are victims of child sexual abuse, and the majority of substantiated cases of child sexual abuse involve the child knowing the perpetrator.

Within the foster care system, the majority of foster children are placed in homes due to maltreatment. Specifically, children are primarily placed in foster care for neglect and physical abuse. In the youth runaway population, almost one quarter elope due to abuse in the home. In the

adult male felon population, 68% report early childhood victimization, particularly physical and sexual abuse. It is notable that the economic burden generated by child maltreatment in the United States is approximately \$124 billion.

Risk Factors

Numerous child, caregiver, and family factors have been identified that are related to an increased risk of child maltreatment. These range from distal factors (e.g., having a history of being abused) to more proximal and amenable factors such as lack of social support, stress, having unrealistic expectations of the child, poor parenting skills, parent's substance abuse, and family discord. The strongest risk factors for child physical abuse are a lack of family cohesion, high levels of family conflict, and a parent's level of anger or hyperactivity. For child neglect, perceiving the child as a problem and a poor-quality parent-child relationship are the strongest risk factors. A child's level of social competency has also been found to be a risk factor for both physical abuse and neglect. Other child risk factors include having a difficult temperament, behavior problems, and medical problems. Finally, children with a history of maltreatment are at risk for revictimization and other forms of maltreatment later in life.

Long-Term Consequences

Child maltreatment is associated with a myriad of negative consequences resulting in medical, physical, social, behavioral, cognitive, intellectual, emotional, and psychological difficulties. There are several factors that impact the effects of child abuse and neglect: the age of the child; the type of abuse; the frequency, duration, and severity of the abuse; and the relationship between the child and the perpetrator. Children who have been maltreated have difficulty with emotion regulation and exhibit socially disruptive behavior problems such as physical aggression. Moreover, emotional regulation difficulties that originate in childhood carry over into adolescence and adulthood. Aggressive children with a history of child maltreatment engage in more severe forms of delinquency as they age, and research suggests that children who have experienced abuse are 9 times

more likely to get involved with the criminal justice system during adolescence.

Child maltreatment is associated with mental health difficulties and higher rates of psychological disorders with elevated risk of developing mood, anxiety, and substance disorders in particular. In fact, of the possible adversities one may experience as a child, abuse and neglect are two of the strongest predictors of developing psychiatric disorders. Mood and anxiety disorders tend to be associated with physical abuse, sexual abuse, and neglect; personality disorders (e.g., borderline personality disorder) are associated with emotional abuse and neglect; and schizophrenia is associated with emotional abuse.

Much of what is known about child maltreatment is specific to sexual abuse. This could be because of those who have been sexually abused, approximately one quarter of them will have lifetime contact with mental health services. Child sexual abuse has been found to be related to anxiety disorders, depression, eating disorders, post-traumatic stress disorder, sleep disorders, parasuicidal behaviors (e.g., cutting), and suicide attempts. Exposure to sexual abuse is also related to psychosis, substance disorders, and personality disorders. Child sexual abuse may be related to worse long-term mental health outcomes relative to physical abuse. Moreover, sexual abuse is a risk factor for the development of subsequent mental health problems regardless of victim gender.

Of course, there is also evidence of a causal relationship between nonsexual forms of maltreatment and a host of negative outcomes (e.g., psychiatric disorders, suicide attempts), highlighting that all forms of maltreatment are important risk factors for adult behavioral health. For example, experiencing physical abuse in childhood is predictive of poor mental and physical health, even decades after the abuse. Specific to emotional abuse and neglect, these experiences are uniquely related to later symptoms of anxiety, depression, and maladaptive beliefs. Thus, each subtype of maltreatment should be considered individually and holistically with regard to psychological development.

In studying this profound relationship between maltreatment and psychopathology, age of onset is a critical variable. To illustrate, earlier onset is predictive of more symptoms of anxiety and

depression in adulthood, whereas later onset may be predictive of more behavioral problems later in life. Specific to sexual abuse, later onset seems to be especially salient to a greater risk of psychopathology.

Maltreatment is strongly related to other negative outcomes in adulthood beyond psychopathology. For example, compared to young adults with no confirmed history of abuse, adults with a history of abuse demonstrate greater overall health difficulties, less educational and economic attainment, and more criminality. A phenomenon referred to as the *cycle of violence* details how child maltreatment may progress to violent and criminal behavior in adolescence and adulthood. Indeed, adversities such as neglect and experiencing and witnessing violence as a child are particularly strongly associated with adult criminal behavior. There are also complications with physical health after maltreatment, such that the magnitude of risk for negative physical health outcomes is comparable to the risk for negative mental health outcomes. For example, there is evidence to suggest that the experience of sexual abuse is related to lifetime diagnoses of somatic disorders. Of particular concern are neurological and musculoskeletal problems, trailed closely by respiratory and cardiovascular issues. Relatedly and as noted earlier, child maltreatment is also associated with suicide attempts and other adjustment difficulties as an adult.

Protective Factors

There is variability among victims of maltreatment with regard to the level of impairment. Not all children respond similarly to abuse and neglect—some may develop long-term consequences, while others display minimal symptoms. This variability has led to the identification of protective factors that may promote resiliency and attenuate the negative long-term consequences of this adversity. In particular, the stability of the family environment and the presence of supportive relationships are consistently identified as protective factors. Moreover, in adulthood, social support is a key mechanism in resiliency to anxiety and depression after childhood maltreatment. Similarly, perceived parental care, positive adolescent and adult peer relationships, and the stability of

adult romantic relationships are related to fewer symptoms of psychopathology. Although positive adaptation in the face of maltreatment is possible, only a minority of adults with an abuse history report no mental health difficulties. Based on what is currently known, social support is key to buffering the effects of child maltreatment, especially for later psychopathology. However, those with a history of maltreatment report having significantly less social support than those without a history.

CHILD PORNOGRAPHY

Child pornography (CP) is readily defined as images that portray the sexual assault of minors. Due to the massive growth of sexual content featuring children that is available on the Internet and the role the Internet plays in driving CP, its possession, distribution, and production, increased

public and law enforcement attention has also been drawn to the issue of child sexual abuse and exploitation. This entry examines the issue of CP from its development in physical media to electronic forms with the Internet. Also highlighted are the amounts and types of CP that exist on the Internet and a profile of those most likely to use it. Because these activities have reached the forefront of law enforcement action and societal concern, this entry concludes with an examination of legal and law enforcement approaches to CP.

Defining CP

One difficulty in the classification of CP as images that portray the sexual assault of minors is determining whether the individual portrayed is actually a child or a minor. Sometimes this is a simple matter, as in the case of very young individuals. It is a bit more difficult, however, with those who are older or who appear older. In these cases, physical features such as body size, waist-to-hip ratio, and genital development may be examined to make a rough determination regarding the individual's approximate age.

From a legal standpoint, the major requirement of defining an image or a video as CP is that a child must be present. In most jurisdictions, a child, or a minor, is defined as someone under the age of 18 years. If a child is present, the next step is to determine whether he or she is being portrayed in a way that could be considered pornographic. Often, pornography is defined along the lines of obscenity or in tandem with notions of sexuality and arousal. Therefore, it is possible for an image to be considered pornography with regard to the sexualized nature of the composition, but not to fall under the rules of pornography as defined by obscenity. Examples of this would be images that focus on the genitalia of clothed children or photographs of children interacting with adults in the context of a nudist colony.

In other words, CP is not an easily defined concept. At the core is the understanding of who is considered societally to be a child. This can differ by *t*, the time period, country, or even jurisdiction. Another complication is determining the types of material considered pornographic. This is also often determined by the social mores of a particular time period or within a specific community.

History

Sexualized images have existed since the beginning of recorded history. While the exact origin of sexualized images of children has not been established, stories and images (drawings or paintings) of sex with children date back as least as far as the 1400s. Erotic material involving children has proliferated throughout history, waxing and waning with regard to appropriateness, depending on changing social values of the time.

The development of the camera, and more specifically film and photographs, ushered in a *golden age* of CP and erotica. With photography, printed images could appear in mass-produced books and magazines, often easily obtainable and publically traded or purchased in stores. Many of these magazines, with names such as *Nudist Moppets* and *Bambina Sex*, were produced in Europe. Eventually, due in part to reports (sometimes erroneous or exaggerated) regarding the number of children involved in the production of CP and the amount of money being made off of their participation, the tide of social acceptance began to turn. This culminated with the passage of several laws, including the Protection of Children Act of 1978 in the United Kingdom and the Protection of Children Against Sexual Exploitation Act of 1977 in the United States.

The advent of the Internet and the spread of digital cameras and media facilitated the anonymity and affordability of CP. Prior to the Internet, obtaining child exploitation images required either producing it oneself or contacting brokers, often through classified advertising. Both of these methods provided opportunities for detection and arrest. The net effect of this risk for arrest and the difficulty in obtaining material was that CP became a risky and an expensive venture. However, with the advent of the Internet, individuals interested in obtaining CP were afforded a heretofore unseen level of anonymity. The Internet provided a high degree of availability and affordability as well.

With regard to availability, it is evident that sexual materials, both legal and illegal, are readily accessible to anyone with a computer and access to the Internet. One of the main reasons for this is the nature of digital images and film. What once needed to be photocopied and passed around by

hand or through e-mail could now be digitally copied, with little to no degradation in quality, and passed along computer networks at fast speeds. Along with this ease of image accessibility, creating and maintaining collections of CP material also became easier due to increased storage capacity and decreased costs of hard drives and attendant technologies. Additionally, the Internet is *always on*. Interested individuals need only to pull up a browser or start any number of chat room software programs at any time to begin the process of obtaining and/or distributing CP.

Furthermore, the anonymity of the Internet has substantially decreased the risk of detection. This is not to say that the trafficking and collecting of child pornographic images are risk free, but given the myriad ways of anonymously traveling the digital highways of the Internet, it is relatively easy to operate undetected. As the technology develops over time, law enforcement is given new tools with which to make anonymity less certain. However, technology devoted to hiding one's true identity also progresses at almost the same pace, the Dark Web and browser anonymizers such as Tor being two of the more recognizable examples of this trend.

The combination of availability and anonymity has made the collection and storage of CP not only easier to do but also more affordable. Computers are readily available, if not in homes, then in public libraries or Internet cafes. Connection to the Internet, through an Internet service provider, becomes more and more affordable as it increasingly becomes a part of everyday life. Before the onset of the digital age, an individual was able to buy a magazine or a book with relatively few CP images. The cost of this book was approximately the same as one might have paid in the mid-2010s for a month of Internet service, offering potential access to thousands, if not tens of thousands of similar images.

Content and Typologies of CP

Analyses of thousands of pictures and videos of CP have yielded remarkably consistent results as to the nature and content of these images. Most typically, the individuals shown are prepubescent children who are overwhelmingly female. Research also shows that the typical child is smiling or does

not appear to be in distress, suggesting that only a small minority of those who consume CP are interested in seeing a child in depictions of sexual violence or sadism. This is not to say that images of sexual violence do not exist in the typical offender's collections, rather that it was not the overwhelming focus of their interests.

Other studies have categorized types of CP, based on the degree of victimization displayed in the image or video. One common taxonomy was developed by the Combating Paedophile Information Networks in Europe project. This approach utilizes 10 categories that start with images that are indicative of sexualization, such as those showing children in their underwear or swim clothes. They continue to nudist categories where naked children are shown in appropriate settings and then to erotica where nude and/or seminude children are shown in provocative poses or with a particular emphasis on their genitals. The final categories are those where actual physical or sexual assault occurs, with the last category being reserved for those images where the child is purposively being shown in situations where they experience torture or some other form of sexualized violence.

Amount of CP Online

As with many forms of illegal sexual deviance, much of the information about the prevalence of CP comes from sources in contact with the legal system. To a large extent, then, the degree to which child exploitation images exist outside of this legal context, while undoubtedly larger, is unknown. What is known is that there are individuals and groups dedicated to the trafficking and collection of CP images in almost every corner of the Internet.

Although CP is widespread across the Internet, the availability of these images has declined since the early 2000s. The main reason for this is the increased attention on them from the law enforcement community. A number of high-profile cases and prosecutions, coupled with a dramatic increase in penalties, have driven child abuse images into the darkest regions of the Internet. This is not to say that the number of images has decreased, however. It is likely that the absolute number of CP images and videos has grown: Old content is

traded, downloaded, and stored on countless hard drives and servers around the world. New images are uploaded and dispersed through anonymous e-mail clients and encrypted browsers.

Consumers of CP

As the amount of CP has grown over the years, a distinct profile of the typical consumer of sexualized images of children has emerged, particularly in terms of gender, age, education, race, and marital status.

Gender

The typical consumer of CP is male. This is the strongest correlate of offending behavior and is consistent across other types of sexual offending as well. This is not to say that there is a complete lack of women in CP offending. Rather, a relatively small number of women have an interest in CP from the clinical perspective (that being someone sexually interested in children) or were serving in a supportive role for the male by grooming or obtaining children for production purposes.

Age

The typical CP offender is slightly younger than the general population or that of the contact sexual offender (i.e., sexual offense in person). Because CP is accessed mainly through the Internet, this is likely due to the tendency toward greater technology fluidity by younger persons than those of older generations.

Education

Compared with contact sexual offenders, those who use CP are likely to be more educated. As with age, this is likely the result of the type of person more likely to use the Internet and related technologies. The more education a person receives, the more likely this person will be Internet-savvy.

Race/Ethnicity

The overwhelming majority of these individuals are non-Hispanic Whites. While somewhat unclear as to why racial or ethnic differences exist among CP consumers, the most likely explanation

for this is the disparate use of the Internet among those of various backgrounds.

Marriage

CP offenders are less likely to be married as compared to people in the general population. One explanation for this is that these offenders are more likely to have issues relating to interpersonal interactions, social skills, and self-esteem as compared to their nonoffending counterparts in the general population. It is also possible that those who consume CP, who have a sexual interest in children, are less likely to form bonds with similarly aged adult partners and are therefore less likely to marry.

Law Enforcement and Legal Responses to CP

Prior to the development of the Internet, the normative method of transmitting CP images was, if not exchanged in person, through e-mail. Consequently, the responsibility for investigating and apprehending individuals involved in CP fell largely upon postal inspectors. As the Internet expanded and the technologies associated with it grew more sophisticated, law enforcement strategies were forced to adapt. As more individuals began accessing and collecting CP images online, law enforcement officials began scouring chat rooms, image-sharing services, and other corners of the web in an effort to track down those trading in illicit images of children. Numerous agencies in the United States, from the U.S. Marshals to the National Center for Missing and Exploited Children, along with the Internet Crimes Against Children Task Force, have increased attention and resources on the problem of CP.

In addition to the front-end law enforcement strategies, the U.S. federal criminal code has also expanded to include broader categories of sexual offenses and lengthened sentences associated with them. For example, the PROTECT Act of 2003 increased the maximum sentence for the production of CP as a first offense from 20 to 30 years. A new mandatory minimum sentence of 5 years was created for the receipt and distribution of CP. Additionally, judges could exercise discretion to extend the term of postrelease supervision to a maximum of life. This had the effect of

dramatically increasing terms of postrelease supervision for CP offenders, who had previously been subject to a maximum term of 5 years.

CHILDREN OF OFFENDERS

Children of offenders incur a host of disadvantages as a result of a parent's criminal behavior and criminal justice involvement. Of particular concern to researchers and policy makers are children whose parent's criminal behavior has resulted in incarceration. A growing body of work identifies parental incarceration as a leading contributor to social and economic inequality. This is because parental incarceration affects children in ways that adversely affect children's life course trajectories. This entry focuses on the short- and long-term implications of parental incarceration on issues related to children's welfare such as behavior, mental health, educational outcomes, and economic well-being.

Children of Offenders in the United States

In the United States, most incarcerated parents are parents. Surveys of prison inmates reveal that approximately 52% of state inmates and 63% of federal inmates are parents to minor children and that many of these parents have more than one child. Rates of incarceration have increased among mothers and fathers in recent decades, but fathers constitute the bulk of incarcerated parents. Research shows that most mothers and

fathers were involved in their children's lives before they were incarcerated, with many children residing with or otherwise economically supported by their parents prior to their parents' incarceration.

Recent estimates of incarcerated children suggest that 2.7 million, or one in every 28, U.S. children have a parent who is currently incarcerated. Nearly 10 million children have experienced a parent's incarceration at some point during their childhood. While incarceration has become a more common experience among U.S. children in recent decades, parental incarceration is not equally distributed across children. Black and Latino children are disproportionately affected by parental incarceration; Black children are 7½ times more likely than White children to have an incarcerated parent, and Latino children are 2½ times more likely than White children to have an incarcerated parent.

Trauma and Stigmatization Associated With Parental Incarceration

Before parents are incarcerated, they are arrested. Aside from the incarceration, a parent's apprehension often creates a traumatic and confusing situation for children. This is true even for children who do not witness their parents' arrest. For children, a parent's apprehension is often abrupt and unexpected because children are often not privy to their parent's criminal behavior.

Displacement is one of the ways in which a parent's arrest and subsequent incarceration are traumatic for children. Children often become displaced from their familial home following their parents' arrest, and many children are relocated to homes that are underprepared financially for their arrival. While most children remain with their mother during their father's incarceration, children whose mother is incarcerated rely largely on grandparents, friends, and relatives and the foster care system for childcare during their mother's imprisonment. One in four children who reside with grandparents during their parents' incarceration lives in poverty, and many experience unmet financial and material needs. As children wrestle with making sense of their new life without their parent, their behavior can change in detrimental ways with some children beginning to act out behaviorally (i.e., aggressive; externalizing

behavior problems), while others suffer in silence (i.e., internalizing behavioral issues).

Not only must children cope with physical and emotional losses associated with their parent's arrest and subsequent absence, many must also endure social consequences stemming from having a parent who is incarcerated. The available literature suggests that incarceration is stigmatizing to offenders *and* to those who are connected to them by familial ties, including their children. Incarcerated children and families experience stigma from peers, teachers, family members, and others in the community. In this way, incarceration serves as a double blow to incarcerated children by removing a parent from their lives and by stigmatizing them and their families at a time when they need encouragement and support from others. The exodus of people from children's lives and the isolation that often results can exacerbate the detrimental consequences associated with parental incarceration.

Consequences of Parental Incarceration for Children's Behavior

Research shows that parental incarceration often leads to children's externalizing behavior issues. The effects of parental incarceration on children's behavior have been observed across developmental stages from early childhood to adolescence. Increased levels of aggression, disruptive behaviors, and problems with attentiveness have been observed among young children who have a parent who has been incarcerated. These outcomes have been observed even as early as age 3. Compared with children who have been separated from their parent for other reasons, children with a parent who has been incarcerated are more likely than their counterparts who have not experienced a parent's incarceration to commit a range of delinquent acts including drug and alcohol abuse, truancy, gang involvement, fighting, prostitution, and violence. Other externalizing behaviors among youth who have a parent who has been incarcerated include sexual promiscuity and teenage pregnancy.

Some of the aforementioned externalizing behavioral issues may stem from both parental absence and the stigmatization associated with parental incarceration. The incarceration of a parent does not carry as much positive sentiment and social

support as other situations involving parental loss such as divorce or death. While some children display feelings of vulnerability, others face their challenges through aggressive and disruptive behaviors. As such, some children develop retaliation toward others, experience pent-up and explosive anger, have low self-esteem, and engage in behaviors that undermine their childcare arrangements.

Researchers and policy makers concerned with the intergenerational transmission of crime from parents to offspring have devoted much attention to investigating whether children of incarcerated *themselves* are likely to be incarcerated in the future. This body of research has produced mixed results. Nevertheless, there is research suggesting that children of incarcerated are 5–7 times more likely to be incarcerated than their peers whose parents have not been incarcerated themselves. Other research suggests that one in 10 children who have a parent who has been incarcerated will be incarcerated themselves before reaching adulthood.

In addition to external displays of problem behaviors, children of incarcerated experience internalizing behavioral issues. These issues have also been observed across developmental stages. Inmates' children often develop anxiety and fear about their parent's absence, and their inability to regularly communicate with their parent solidifies these emotional outcomes because children are left to wonder about their parent's welfare while incarcerated. Young children and adolescents are likely to experience depression as a result of their parent's incarceration. Inmates' children are also likely to experience separation anxiety, impaired socioemotional development, traumatic stress, and survivor guilt during and following their parent's incarceration. Young children are especially vulnerable to outcomes such as developmental regression, poor self-concept, and acute reaction and inability to overcome future traumatic and stressful situations.

Consequences for Children's Educational Attainment

Parental incarceration creates difficulties for children to be socialized through mainstream institutions such as schools. These children often have lower educational performance partly because some children experience academic disruption as they move to new schools and neighborhoods.

Research shows that when compared to children whose parents have not been incarcerated, children who have an incarcerated parent are more likely to have extended absences from school, more likely to drop out of school, less likely to graduate from high school, portray lower cognitive abilities, and have delays in learning. These outcomes are typically observed 1–4 years after a parent has been incarcerated. As a result of their poor academic performance, incarcerated children are often held back a grade. Behavioral problems stemming from a parent's incarceration also make school less manageable for incarcerated children. Research shows that these children are significantly more likely than those who have not experienced parental incarceration to be expelled or suspended from school.

Parental Incarceration and Children's Economic Well-Being

Children of offenders often struggle financially both during and after a parent's incarceration. During incarceration, parents are hindered from contributing household income or child support to their families and children. This means that a parent's arrest and subsequent incarceration automatically reduce financial support for some children.

In addition to limiting the economic support parents contribute to their children, parental incarceration places increased demand on children's already-stretched resources. Maintaining contact with an incarcerated parent is a costly endeavor; visiting mothers and fathers, who are often housed at far-flung facilities, demands resources that may be hard to come by or might be needed to promote child and family well-being (e.g., pay a bill and purchase necessary items). In some cases, the cost of a parent's legal representation is another added expense spurred by incarceration that children's families must endure.

The financial losses associated with parental incarceration have been associated with a number of deleterious outcomes for children. Research shows that children of incarcerated are more likely than other children to experience food insecurity, material hardships, and even child homelessness. The risk of experiencing financial insecurity does not significantly improve when parents are

released from prison because having an incarceration history reduces parents' access to employment in the regular sector and wages that can sustain a family.

Parental Incarceration: Implications for Children's Well-Being Across the Life Course

The problems associated with parental incarceration vary considerably in complexity and severity for children, but the detrimental effects of incarceration in early childhood and adolescence can reverberate throughout a person's life course. Children who do not experience attachment and supervision from their parents are at a higher risk of emotional and behavioral problems during their lives. Aggression toward others, for example, can lead to outcomes such as substance abuse and contact with the criminal justice system in early adulthood. Parental incarceration also increases the risk of long-term mental health issues as children grapple with memories of a parent's arrest, criminal behavior, and incarceration.

Importantly, too, parental incarceration hinders children and parents from developing and maintaining a strong parent-child relationship. The level of contact between children and their incarcerated parent depends on factors such as school hours, children's distance from the jail or prison facility, and compliance from children's caregivers. As a result of the challenges associated with maintaining a parent-child relationship, some children redefine their perceived closeness with their parent.

Children's views vary toward their parent's incarceration and the challenges related to their parent's reentry postincarceration. Whereas some children are optimistic about assisting with their parent's desistance from crime and reentry, others worry about their parent's potential for future contact with the criminal justice system. The effects of parental incarceration on the parent-child relationship are sometimes so severe that some youth choose to prematurely terminate their dependency relationship with their parent, which can have implications for the intergenerational crime and their own risk of incarceration.

CLASSIFICATION

Classification is the systematic assignment of entities to homogeneous categories, groups, or types according to specified rules or parameters. By formulating classification systems for crimes, criminals, and patterns of criminal behavior, criminologists hope to increase their understanding of these phenomena. Taxonomies are comprehensive

systems that seek to categorize a broad array of phenomena. Syndromes are narrower in scope. Categories can be formulated heuristically on the basis of psychological or criminological theory or empirically on the basis of observations. Any shared characteristic can serve as the basis for a classification system as long as those assigned to each category have more in common with each other than those placed in other groups. Successful systems are valid, are reliable, and make a contribution to knowledge, as well as being practical and useful.

Fundamental to human knowledge, classification probably began with the rudimentary differentiation of plants as edible or inedible and animals as predators or prey, eventually evolving into the complex systems that are today the basis for all scientific inquiry. The essential feature of classification is that the members of each group are relatively homogeneous and share more characteristics with one another than they do with those assigned to other groups and categories. By studying the similarities within groups and the differences between groups, criminologists hope to further their understanding of criminals and their behavior. They investigate such issues as the antecedents of different types of criminal behavior, how patterns of offending vary across cultures and subcultures, and what interventions work best with different types of behaviors. In applied settings, such as correctional facilities, classification is used to assist in management and treatment decisions such as which offenders should be placed on probation or incarcerated.

Taxonomies are comprehensive classification systems that seek to categorize a wide range of entities. Over the years, numerous taxonomies of crimes and criminal offenders have been postulated. Many are hierarchical with broad categories being differentiated into smaller, even more homogeneous subgroups. For example, a system that differentiates crimes against people from those against property might subdivide the latter into those in which the victim is present, such as robbery, from those in which the victim is absent, such as burglary. Less comprehensive classification systems may focus on particular syndromes rather than the whole array of crimes or criminals, for example, differentiating overcontrolled from undercontrolled violent offenders.

Whether they are taxonomies or syndromes, classification systems may be created heuristically or empirically. Heuristic or theoretical systems follow the principles of deductive logic with categories derived from constructs such as those found in theories of personality or criminology. Empirical systems utilize inductive logic and are based on observed patterns of covariation, such as those revealed by systematic observation or by statistical techniques such as a factor or cluster analysis. Some approaches employ a combination of these approaches.

Any shared characteristic or a set of characteristics can be used as a basis for classification, and many have been proposed. Differentiations based on age, gender, and types of offense are so widely used as to be almost universal. Juveniles are typically processed differently from adults, men and women are usually housed separately, and the more violent and arguably dangerous offenders are often segregated and confined more securely than those judged to be less of a threat to one another and society.

More detailed criminal classification systems have been based on a wide variety of variables. They include schemes constructed using constitutional or physiological factors; groupings based on cognitive functioning; categories using physical, emotional, and interpersonal maturity levels; types based on the current offense, repetitive crime patterns, and criminal careers; categories postulated on the basis of demographics, social class, and subcultural values; as well as groupings derived from psychological, psychiatric, sociological constructs, to list just a few.

While all these factors can be and have been used as the basis for classification, in the U.S. criminal justice system, ethical considerations of social justice and equity prohibit using variables such as race, religion, wealth, and family status to guide the treatment of criminal offenders.

The value of a classification system must be established through empirical research. The first test is validity, determining whether the hypothesized categories actually exist, whether the members of each group really have the postulated attributes or traits, and whether they differ in this respect from other groups.

The second issue is reliability. For a system to be useful, raters must be able to assign events or individuals to the specified categories consistently.

Reliable classification requires clear operational definitions of the categories with carefully specified objective rules or scoring principles. Different raters working in different settings must be able to agree on the designation of each case. In taxonomy, all cases must be assigned to some category.

A third question is heuristic value, whether the proposed system advances criminological research, helps explain observed phenomena, leads to new insights, or advances theory. Determining the heuristic value of a system requires the accumulation of a body of empirical research over time.

Utility is a fourth consideration. Useful systems contribute to criminal justice and correctional decision-making such as assisting in inmate management and treatment or lowering parole recidivism.

A fifth issue is practicality or cost-effectiveness. Other things being equal, systems that can be easily implemented and use information that can be readily obtained at low cost will be preferred. Computer-based classification systems are typically more economical than those requiring extensive training of human raters.

Although many criminological and psychological taxonomies and syndromes have been proposed over the years, relatively few have actually been systematized, defined, validated, or implemented. Those few, however, have greatly contributed to our ability to understand and deal with criminal behaviors and offenders.

COERCED CONFESSIONS

A coerced confession is an involuntary confession. Coerced confessions are elicited by investigating officers' use of coercive tactics. Coerced confessions

are sometimes authentic but are often false. In addition to true, but involuntary confessions, there are two different types of false coerced confessions: coerced-compliant and coerced-internalized. Coerced confessions are an important topic in criminal psychology because any suspect interrogated by police officers could be coerced into making an involuntary confession. False coerced confessions can lead to wrongful convictions, which pose serious problems for the criminal justice system. This entry describes the coercive tactics investigative officers may use, the different types of coerced confessions, the role of coerced confessions in the court system, and coerced confessions in psychological research.

Coercive Tactics

Coercive tactics are designed to compel, control, and/or intimidate. Coercive tactics are often used by police officers during interrogations of suspects. It is important to note that some interrogative tactics considered coercive are accepted legally, while other coercive tactics are not.

Illegal Coercive Tactics

In many countries, confessions provided under the promise of leniency or stemming from the use of quid pro quo tactics—that is, explicit offers of benefit in exchange for admissions of guilt—are inadmissible in a court of law. Similarly, in most countries, any statement following the use of physical force or explicit threat of physical force by the police would be inadmissible.

Legal Coercive Tactics

There are a number of coercive interrogation tactics that are permitted by the courts; however, specific coercive tactics considered legally acceptable vary noticeably by jurisdiction. A confession resulting from legally acceptable coercive tactics would generally be considered admissible. This is true even if the resulting confession was false. Throughout North America, and in many other jurisdictions, police officers are allowed to make strong accusations, manipulate individuals, invade personal space, psychologically pressure the suspect to tell the truth, and use lies or other forms of deception. Using false evidence ploys, officers may deceitfully imply to the suspect that

they have evidence tying the suspect to the crime. For example, an investigator may falsely tell a suspect that there is forensic evidence (e.g., fingerprint, DNA, or fiber match evidence) that incriminates the suspect or that there are eyewitnesses who have identified the suspect. Trickery and other psychologically manipulative tactics are generally accepted as legal within the court system, as it is assumed that the tactics would not influence innocent suspects to falsely confess. Although research has shown that these tactics may lead to a coerced false confession, they may also lead to a true confession, and it is nearly impossible to tell the difference between the two or to know the rates of coerced false confessions.

Coercive Interrogations

The Reid technique is a form of investigation often used by police officers, which employs coercive tactics. John E. Reid created the Reid technique in the 1990s. This technique is based on three basic themes: isolation, confrontation, and minimization. Isolation includes both physical isolation and psychological isolation of the suspect. Confrontation techniques are based on strong assertions of the suspect's guilt as well as physical intimidation. Minimization involves psychological and moral justifications for the crime as well as subtle suggestions of leniency.

The Reid technique includes many different strategies that are organized into a general framework of interrogative stages. In the early stages of the interrogation, officers will isolate a suspect for a period of time in an interrogation room. Next, officers will insist to a suspect that there is no doubt about the suspect's guilt, while confronting the suspect with evidence. Evidence may be real and/or exaggerated or outright false. During this confrontation, interrogating officers may also use other maximization techniques designed to intimidate the suspect. In the later stages of the interrogation, investigators will pressure the suspect to tell the truth in the form of a confession. When encouraging the suspect to confess, interrogators use minimization techniques designed to decrease the suspect's perceived seriousness of the situation. Officers may suggest to the suspect that just telling the truth, in the form of a confession, will be easier on the suspect (e.g., statements along the lines of "things will go better for you if you just

tell the truth and confess"). Police may also tell the suspect that they will make sure the suspect receives psychological or spiritual help. Interrogations can be very lengthy, and investigators can become very aggressive and confrontational with suspects.

Research has linked the Reid interrogation technique to false and coerced confessions. False and coerced confessions have also been associated with lengthy and confrontational interrogations. It is becoming common for police interrogations to be videotaped. Videotaped interrogations allow experts to assess the interrogation for coercive tactics and to evaluate the confession for markers of reliability or inconsistencies. It should be noted that experts are often unable to definitively establish a confession as false without other evidence exonerating the suspect.

Coerced-Compliant Confessions

Coerced-compliant confessions are false statements made under duress or pressure from coercive interrogative tactics. Individuals who have made a coerced-compliant confession know they are innocent and falsely confess to the interrogating officers in order to escape the aversive interrogation situation and/or gain some suggested benefits. A suspect who maintains his or her innocence throughout a lengthy interrogation can increase the aggression and pressure from investigating officers, who believe that the suspect is guilty. Generally, a person who makes a coerced-compliant confession has a goal of ending the interrogation, getting out of the interrogation room, and being able to go home because he or she believes that confessing will reduce the potential punishment. The suspect often does not realize the consequences of making a confession and may believe that if he or she says what police want to hear, then he or she will be allowed to leave the interrogation. Often, these individuals believe that they can recant their confession afterward and that their innocence will be recognized by the justice system.

Coerced-Internalized Confessions

A confession is considered to be coerced-internalized when an individual comes to believe that he or she committed a crime for which the individual is actually innocent. Coerced-internalized

confessions share many aspects of coerced-compliant confessions (e.g., the person is under duress from interrogators), but they are distinct in that the suspect comes to develop a false memory of committing the crime. Research has demonstrated the malleability of human memory and the phenomenon of false memories. Suspects who make coerced-internalized confessions are not necessarily confessing to achieve a goal; these individuals truly come to believe that they are responsible for the crime. Often, police will use tactics such as lying to the suspect and telling the suspect that there is either eyewitness or forensic evidence tying the suspect to the crime. Some circumstances can make a person especially vulnerable to coerced-internalized confessions, such as experiencing memory problems, being under the influence of medications or illegal drugs which impair memory, being severely tired, or being especially anxious and confused. Often, individuals who give a coerced-internalized confession are highly suggestible and can be from vulnerable populations including persons with learning disabilities.

Coerced Confessions in the Court System

A confession is powerful evidence against a defendant during a criminal trial. When a confession is a central piece of evidence against a defendant, it is up to the judge to determine whether the confession is admissible. Admissibility rules vary by legal jurisdiction. The criteria for determining the admissibility of a confession are generally based on whether the statement was voluntary or due to coercion, and that determination is evaluated on the totality of the circumstances. If a confession was obtained through the use of coercion, a judge further assesses the confession to identify whether illegal coercive tactics were used. In addition, confessions are usually evaluated for markers of accuracy, such as corroboration by other evidence.

If a suspect is convicted of a crime based on a coerced confession, it is likely that the conviction would be upheld in appellate courts, even if the individual recanted the confession. If a confession is retracted, and the individual who gave the confession is adamant, it was coerced, and given under duress, additional issues arise. If the defendant is on trial by jury, there is a question of how

well the juries are able to understand what a coerced confession is and apply that understanding in their judgment. In the courtroom, the judge ultimately is in control of whether evidence requires interpretation by an expert witness. Researchers have recognized the importance of having an expert witness testify about the psychology of interrogations and coerced confessions to help the jury understand the circumstances.

If a coerced confession is used as evidence against an innocent person who is convicted, this poses two large issues within the justice system. First, an innocent person can be sent to prison for years based on coerced confession evidence. Even when an innocent person who was wrongfully convicted is later exonerated, his or her life may never return to normal. The time spent in prison, and strain on family and loved ones of the wrongfully convicted, can uproot and change a person's life forever. The second issue that arises when an innocent person is wrongfully convicted is that the real perpetrator does not justly receive legal punishment for the crime. In addition, it is possible that the real perpetrator may still be in the community, committing further crimes. Often a confession, even a coerced confession, will end an investigation. If investigators believe that they have caught the perpetrator and that individual confesses, they usually will not continue to investigate other suspects.

Prevalence of Coerced Confessions

It has been well established that coercive tactics used by interrogating officers can lead to coerced false confessions; however, it is difficult to tell how often coerced confessions occur. Usually, confessions can only be determined to be false based on clear physical evidence that the individual in question was not the perpetrator or through clear evidence that another person committed the crime. Generally, DNA evidence is the only distinguishing piece of evidence to exonerate an innocent person who gave a coerced false confession. According to the Innocence Project, an organization that helps exonerate falsely imprisoned people in the United States, as of January 2016, 27% (or 88 cases) of exonerations of the wrongfully convicted included evidence of false confessions or admissions of guilt.

Coerced Confessions in Research

False confessions, including coerced confessions, have been studied extensively by psychologists. There are several researchers widely recognized as leaders in the area of interrogations, false confessions, and coerced confessions. These experts have conducted many studies, and written authoritative reports, on false and coerced confessions. Once a confession is on the record, it is almost impossible to distinguish a false confession from a true confession. Research has shown that innocent people sometimes make false confessions; however, many people cannot understand how this could happen. When asked, participants recognized that coercive tactics may lead to a confession but mainly believed that coercive tactics would not lead to a false coerced confession. Furthermore, it was easier for participants to deem a confession as false when explicit acts of police coercion were used as compared to subtle acts of coercion. Researchers have also demonstrated that when participants falsely confess in experimental scenarios, some internalize their confession (i.e., come to believe that they committed an offense for which they were factually innocent). Comparisons between samples of the general public and police officers have demonstrated that officers are generally no better than the public at detecting false and coerced confessions; however, officers are more confident in their judgments. Moreover, research has also indicated that regardless of whether a confession is designated as coerced, jurors often do not discount the confession appropriately.

COGNITIVE BEHAVIORAL THERAPY AND SOCIAL LEARNING THEORY

Cognitive behavioral therapy (CBT) and social learning theory (SLT) originated in the larger field of behavioral psychology. Unlike psychoanalytic psychology, which emphasizes the importance of unconscious processes on an individual’s emotional and behavioral patterns, behavioral psychology emphasizes the importance of learning experiences in shaping emotional and behavioral patterns. SLT has been used to understand how individuals acquire healthy lifestyles, as well as mental health problems and antisocial behavioral patterns. CBT is a type of psychotherapy based on SLT principles. The dissemination of CBT into criminal psychology has included treatment for common mental disorders such as anxiety and depression in correctional settings, as well as the application of CBT to specialized treatments for antisocial behavioral patterns (including anger management, violent offending, and sex offending) for juvenile and adult offenders. Overall, research has found CBT to be an effective form of treatment for reducing reoffending and improving a variety of psychological disorders found in offender populations.

SLT

There are three main models of learning within behavioral psychology: operant conditioning, classical conditioning, and SLT. Operant conditioning explains an individual’s behavior as a function of her or his experiences with observable reinforcements and punishments: A behavior that

is followed by a positive consequence is more likely to be repeated, while a behavior that is followed by a negative consequence is less likely to be repeated. Classical conditioning emphasizes associations between two stimuli resulting in a new learned response. For example, a dog trainer might ring a bell before giving a dog a treat. Over time, the sound of the bell will be enough to entice the dog to come. In both operant conditioning and classical conditioning, internal processes that are unable to be observed (e.g., drives, needs, and thoughts) are considered unnecessary to explain behavior. SLT, on the other hand, emphasizes the importance of an individual's thoughts (also known as *cognitions*) and social interactions in addition to observed reinforcements, punishments, and automatic associations in explaining behavior. For example, an individual's learning can be influenced by vicarious learning or by modeling (e.g., learning by watching others) and shaped by various cognitive processes. Expectations that arise from observed consequences of an individual's behavior, positive or negative evaluations of an individual's own behavior as well as the behavior of others, and attributions of causes of behavior of self and others are some of these cognitive processes.

While SLT was not specifically created to understand criminality, psychologists Don Andrews and James Bonta drew upon SLT as well as the scientific research on the established predictors or risk factors of criminal behavior in developing their General Personality and Cognitive Social Learning model of criminal behavior. The primary risk factors (also known as the *Central Eight*) include having a history of antisocial behavior, antisocial personality traits, spending time with criminal friends, thinking patterns that justify and provide a motive for criminal behavior, substance abuse, dysfunctional family relationships, poor performance and attitude regarding school/work, and unproductive use of leisure time. The General Personality and Cognitive Social Learning helps explain how risk factors for crime can lead to, and maintain, criminal behavior through cognitive processes, reinforcement, and modeling. For example, an adolescent may learn how to steal a car by watching his criminal friends break into a car and take it for joyride (*modeling*). The adolescent may enjoy the rush of excitement

from driving in the stolen car and experience a heightened sense of comradery with his friends who all express a sense of achievement in the night's activities (*positive reinforcement*). If they are not caught, then there will be little to deter them from engaging in car theft in the future (*lack of punishment*). Over time, the mere presence of this group of friends triggers a sense of energy and excitement, leading the adolescent to engage in risky activities when she or he is with them (*classical conditioning*). Although the adolescent is keenly aware that this behavior is against the law, she or he may evaluate the theft in a positive manner and think of the victim as foolish for leaving the car on the street instead of in a secure parking lot (*cognitions*). All of these learning factors (operant conditioning, classical conditioning, and SLT), several of which are related to the adolescent's connection to criminal friends, make it likely that the behavior will be repeated in the future.

CBT

While SLT provides a model for how behavioral patterns are developed and maintained, CBT provides a model for changing these patterns by altering the cognitive processes, reinforcements, and learned associations that established the behaviors in the first place. CBT was pioneered by Albert Ellis, a psychologist who developed rational-emotive behavior therapy, and by Aaron Beck, a psychiatrist who developed cognitive therapy. While models of CBT continue to be developed, those established by Ellis and Beck remain the most prominent and provide templates useful for understanding new CBT models. The underlying premise in both Ellis's and Beck's models is that psychological problems can be improved by altering unhealthy cognitions. Therefore, treatment involves helping clients develop an awareness of the irrational or distorted nature of their thinking patterns and then challenging or testing the accuracy of these patterns to remove their negative influence.

Ellis's overarching model of treatment is that irrational thinking patterns such as *demandingness* (insisting that people and situations conform to one's own desires), *awfulizing* (exaggerating the consequences or hardships of unpleasant or challenging situations), *low frustration tolerance*

(underestimating one's ability to cope with setbacks and problems), and *self or other rating* (unreasonably blaming other people or oneself) are the cognitive constructs that underlie human problems. Rational-emotive behavior therapy involves helping clients think more rationally and flexibly about adversity and struggle in their day-to-day lives.

Beck's overarching model of treatment is less concerned with the irrationality of a person's thinking patterns and more concerned with the distorted nature and inaccuracy of the thinking. Beck's model distinguishes three different levels of cognitions: (1) core beliefs, (2) intermediate beliefs, and (3) automatic thoughts. Core beliefs encompass our most deep-seated beliefs about ourselves, other people, and the world. In offenders with depression and anxiety, core beliefs are negative, creating a distorted filter through which they see the world. For example, offenders with a core belief that they are inferior will not only have a low opinion on themselves but will also believe that others see them as worthless. Core beliefs produce the next level of beliefs, intermediate beliefs, which lie closer to conscious awareness. These are the various attitudes and assumptions that form the basis for how an individual thinks, feels, and behaves across different situations. Intermediate beliefs are like rules or imperatives that influence one's life trajectory (e.g., "If I'm not in a romantic relationship, I must be unlikable." "If I'm not in control of the situation, then I'm in danger.").

Intermediate beliefs create *automatic thoughts*, which are the quick, evaluative thoughts that spring up in response to different stimuli and form the stream of consciousness that people might say out loud or think to themselves. In depression and anxiety, automatic thoughts occur in predictable ways referred to as cognitive distortions such as *fortune telling* (predicting the future negatively), *mental filter* (focusing on the negatives instead of seeing the whole picture), and *all or nothing thinking* (situations are viewed in only two categories instead of a continuum).

Hallmarks of the CBT approach include the development of an individualized treatment plan for each client that incorporates a clear rationale for those behavior and thinking patterns that become the focal points of treatment. This is

known as *case formulation*. Therapy sessions are structured and organized. Therapeutic tasks often involve coaching clients in building new skills to alter thinking and behaviors in ways that produce improved outcomes. Finally, homework assignments are given to clients to transfer newly learned skills to day-to-day life. In CBT, repeated practice of new behaviors and thinking patterns are critical for success. For example, an offender with depression may be asked to write down when they have a distorted or irrational thought, to note the emotional reaction it produces, and then to generate a healthier and more accurate way of thinking. Over time, the offender becomes less influenced by unhealthy thinking patterns and instead adopts healthier thinking patterns, a process called *cognitive restructuring*.

The behavioral aspect of treatment involves helping offenders learn, engage in, and practice specific behaviors (e.g., time management, dating skills, parenting skills, and assertiveness) that are more likely to lead to desired outcomes and healthier functioning. Because people behave according to their thoughts—and they think according to their behaviors—changes in behaviors will go hand in hand with changes in thinking. For example, offenders may be asked to deliberately schedule a formerly enjoyable and relaxing activity that they have stopped engaging in since the onset of their anxiety symptoms. As changes in the offender's cognitive and behavioral patterns reinforce each other, the reinforcement provided by the new activity (e.g., exercise) will produce a change in thinking ("I don't have enough energy to exercise." to "I feel better when I get out of the house and do something."), creating a self-reinforcing feedback loop. In a general sense, CBT is focused on changing both thinking and behavior.

Applying CBT to Antisocial Behavior

While CBT was initially tailored to the treatment of depression and anxiety, it has been adapted for the treatment of antisocial behavior. Modifying CBT for antisocial behavior involves a shift in how practitioners approach clients and a different focus in terms of the cognitive and behavioral patterns targeted in treatment. Three foundational components form the basis of an integrated forensic CBT approach: (1) enhancing motivation

for change, (2) focusing treatment on reducing criminal risk-relevant factors, and (3) addressing thinking patterns that facilitate antisocial behavior.

Because offenders are often coerced into treatment, they commonly approach treatment with a lack of interest, if not outright hostility. Therefore, one component of treatment is an initial focus on improving motivation to change. This is accomplished through the use of motivational interviewing, a communication style that emphasizes collaborative discussions about why change would be important, as well as how change might occur. The main objective in using motivational interviewing with offenders is to elicit and explore their own motivations for changing their risky and self-defeating behaviors.

Treatment with offenders focusing on the changeable nature of the Central Eight risk factors (with the exception of criminal history) means that their improvement reduces the risk of criminal behavior and reoffending, while their worsening increases the risk for future offending. There is a complex interrelationship, however, between criminal risk factors on treatment. For example, an unemployed offender may spend free time with friends who drink heavily and use drugs. The friends reinforce the offender's unproductive beliefs about work, the offender's drug use diminishes the likelihood of passing preemployment drug screens, and the offender's substance abuse and criminal companions further distance the offender from prosocial family members. Thus, the various risk factors specific to this case impact each other in an interrelated destructive system. On the optimistic side, a positive change in one of these areas could facilitate positive changes in the others. For example, full-time employment would result in less time with antisocial friends, less time to engage in substance abuse, and exposure to new peers who express prosocial thoughts and model more productive lifestyles.

Conceptualizing cognitions that are relevant for offenders can be approached effectively by taking into consideration the empirical literature that has developed around criminal thinking patterns that facilitate antisocial behavior. Many of these patterns are the opposites of those found in people with depression and anxiety. For example, offenders are unlikely to harshly blame and judge

themselves when faced with criticism, as is common in depressed clients. In fact, they may express little concern for the opinions of others or for how their actions affect others. Nor are they likely to overestimate and exaggerate potential dangers, as is common in clients with anxiety difficulties. Instead, offenders may underestimate danger, seeking out risky situations precisely for excitement. These are the patterns targeted in treatment for cognitive restructuring. By improving motivation for change and targeting the behavioral and cognitive patterns responsible for antisocial behavior, CBT can help prevent offenders from returning to the criminal justice system.

COGNITIVE DEFICITS, EFFECTS ON REHABILITATION

Cognitive deficits is a generic term, encompassing impairment to essential areas of brain function, but not defined uniquely by low IQ or intellectual

disability (ID). ID is defined by the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* as impairment of general mental abilities that affects adaptive functioning in three domains: (1) the conceptual domain (language, reasoning, knowledge, and memory skills), (2) the social domain (interpersonal and communication skills), and (3) the practical domain (skills related to self-management and self-care). To meet the strict definition of ID, symptoms should be chronic and evident before the age of 18 years. Depending on the criteria established, individuals with ID are generally considered those with IQs below 70 on standardized measures. IQs from 70 to 85 are defined as being in the borderline range.

Individuals with specific cognitive deficits, on the other hand, may have IQs in the average range or above average range but commonly manifest symptoms of executive function problems, such as impairments in attention control, strategic goal planning, abstract reasoning, cognitive flexibility, and the ability to organize and adaptively use information contained in working memory. Impairments in executive function have been implicated in aspects of criminal and antisocial behaviors featuring poor impulse control, poor consequential thinking, and problems with emotion management. Unlike intellectual deficits, which must be evident in the developmental period, cognitive deficits can also be acquired impairments resulting from the impact of traumatic brain injury; disease processes, including psychiatric conditions; drug and alcohol abuse; and social and psychological disadvantages, such as poverty and substandard education. All these conditions have been found to be elevated in offender populations and are risk factors for antisocial behavior. This entry discusses the prevalence of cognitive deficits in offender populations, cognitive deficits as a risk factor for criminal behavior, consideration on how these deficits can affect response to interventions, and supervision and strategies to assist offenders with cognitive deficits.

Prevalence of Cognitive Deficits in Offender Populations

Firm rates of cognitive impairment among offenders have been difficult to estimate, although they

are thought to be overrepresented in the criminal justice system. Estimates among incarcerated populations vary based on the assessment tools used and diagnostic and classification criteria applied. Large-scale reviews have found that, when defined strictly by IQ, rates range around 2–3%, broadly in line with rates in the general public. It should be noted, however, that in the criminal justice system, most offenders with severe impairments would be diverted from prison or serve their sentences in specialized secure units, and individuals with very low function would be too limited to become involved in criminal activity. Age-related cognitive decline and lower levels of education among the aged are also rarer in offender populations. This selection bias, then, restricts the distribution of IQ scores within incarcerated populations relative to the community and probably underestimates the rates of ID among individuals involved in crime. Prevalence rates should also be understood relative to whether the sample constitutes offenders who are incarcerated, awaiting trial, or on parole or probation. Another consideration is whether the prisons incarcerate offenders with particular profiles (e.g., the facility has a disproportionately higher number of high-security offenders, offenders in special treatment units, or offenders allocated to protective custody).

Some subgroups of offenders may be more likely to be identified as having IDs compared with others. For example, violent offenders, sex offenders, and persistent serious offenders are among the profiles associated with lower cognitive function, although, once again, this is not a universal finding. Researchers examining the link between ID and sexual offending, for example, have noted that the evidence for lower IQ appears to be related to the referral source, with offenders referred from child protection agencies and prosecutors' offices more likely to have scores in the impaired range. Conversely, there is accumulated evidence that higher cognitive function may be a protective factor for the initiation of criminal behavior among at-risk youth and might also be a protective factor for reoffending.

Although there is inconclusive evidence suggesting that offenders have lower intellectual function than nonoffenders (as assessed by standardized IQ measures), there is reliable evidence that offenders

are more likely to manifest specific cognitive deficits. In particular, there is evidence of increased rates of learning disabilities and impairments in executive function related to poor planning and impulse control and aggressive and erratic behavior. These symptoms are associated with higher rates of diagnoses for attention-deficit/hyperactivity disorder (ADHD), fetal alcohol spectrum disorder and alcohol-related neurodevelopmental disability, and traumatic brain injury. Given that cognitive deficits are related to alcohol dependence and ADHD, there are considerable levels of co-occurring mental health problems. For example, a significant percentage of offenders with serious alcohol problems have cognitive deficits, as do those with substantial symptoms of ADHD.

In summary, there is an agreement that the rates of cognitive deficits are elevated in offender populations. However, precise estimates of the prevalence of cognitive deficits in offender populations vary widely due to the heterogeneity of the definitions used to describe cognitive impairment, the range of measures used to assess it, and the offender population assessed.

Association of Cognitive Deficits and Criminal Behavior

There is established literature demonstrating that impaired cognitive functioning plays a role in criminal behavior. The most current explanation of the association between cognitive deficits and crime is that the relationship is multidetermined, beginning with a developmental trajectory involving early neuropsychological impairment (especially lower verbal skills and problems in executive function), school failure, a drift toward antisocial peer group, and, as a consequence, the weakening of prosocial bonds. For those with acquired impairment, the link is more directly related to impaired judgment and poor consequential thinking, planning, and problem-solving skills. These related executive function deficits are implicated in aggressive, impulsive, and erratic behavior. Some have gone so far as to label a constellation of personality changes produced by frontal lobe damage as *acquired sociopathy*. One leading researcher attributed a life-course pattern of antisocial behavior to developmental neuropsychological problems that interact with a criminogenic

environment, culminating in an antisocial personality. Later research also implicated cognitive impairments to adolescent-limited criminality.

Although the relationship may be complex, there is little doubt that impaired cognitive function is a direct criminogenic factor, not only a responsivity factor affecting offenders' response to interventions. Thus, this should be considered in theories of crime causation and in planning intervention strategies to reduce criminal recidivism.

Effects of Cognitive Deficits on Rehabilitation Efforts

The presence of cognitive deficits in offender populations is associated with histories of lower educational achievement, unstable employment history, learning disabilities, and symptoms of ADHD. For those offenders who have severe cognitive deficits, the correctional environment can be especially demanding. Difficulties understanding and abiding by institutional rules and vulnerability to victimization and exploitation can make the prison experience more challenging for offenders with serious cognitive deficits.

There is some evidence that problems in executive function may impair offenders' ability to respond to correctional programming as measured by program completion rates and improvements associated with participation. Standard correctional program components require considerable levels of literacy that can be discouraging to participants and a barrier to their treatment progress. However, correctional programs that focus on self-regulation skills (i.e., problem-solving, goal setting, planning, and consequential thinking) and address substance abuse (particularly alcohol abuse) are appropriate interventions for many offenders with cognitive deficits. Agencies should be mindful, however, that participants with cognitive deficits will require assistance to compensate for lower literacy and attention deficits. For those with the most severe deficits, specially designed correctional programs may be required to accommodate their learning styles. When these provisions are in place, there is encouraging evidence that offenders with cognitive deficits can complete and benefit from correctional programs.

In addition to programs that directly target factors related to unstable employment history, low

educational attainment, and ADHD symptoms can block opportunities for offenders with cognitive deficits to attain prosocial goals once released. Therefore, vocational training, educational upgrading, and job skills coaching that prepare offenders for community employment are appropriate targets for intervention to reduce future recidivism and improve reintegration potential.

Offenders with cognitive deficits pose a greater challenge to institutional or community management. They can have more trouble adjusting to the constraints of incarceration and increased difficulty following the institutional rules and managing relationships with other offenders. Their rates of institutional misconducts and the severity of the incidents, therefore, are generally greater than those of offenders without these deficits. This finding is consistent with research showing that cognitive deficits are associated with poor social adjustment across a variety of contexts. An understanding of the behavioral patterns associated with severe cognitive deficits could facilitate informal resolution when institutional incidents arise.

Because of higher risk ratings and institutional adjustment problems, offenders with cognitive deficits tend to serve a larger proportion of their sentences prior to being given their first release. This can mean that they are not afforded the same period of time to be supervised and receive the benefit of services from correctional agencies before their sentences are completed. On release, their outcomes tend to be poorer, reoffending and returning to custody at rates higher than those without deficits. This suggests that, in addition to the social and vocational training support required to meet their considerable needs, they require a higher level of monitoring and supervision in the community. Provisions are needed to broker longer-term services from agencies that provide assistance after the mandate of correctional agencies expires.

It should be noted that the contribution of cognitive deficits to the prediction of future offending behavior is much less significant than that provided by standard measures of criminal risk and need, which are composite constructs composed of a number of well-established factors related to correctional outcomes. Still, the overall view of the latest literature is that the level of cognitive function is independently related to correctional

outcomes, even when risk and need are considered. In knowing this, staff have valuable information that can assist them in case planning, accommodation of correctional program delivery, and aiding these offenders in their reintegration efforts.

COGNITIVE DISORDERS IN INCARCERATED OFFENDERS, TREATMENT OF

Mental disorders are frequently associated with varying degrees of neurological impairment that pose serious problems for an individual's ability to self-regulate, avoid self-defeating behaviors, and attain prosocial goals. The term *intellectual disability* specifically refers to impairment in functional domains usually associated with IQ scores below 70. *Cognitive deficits*, however, is a more generic term, also encompassing impairment to essential areas of brain function, though not defined uniquely by low IQ. Individuals with cognitive deficits may test in the average range or higher, but they commonly manifest symptoms of executive function problems such as impairments in attention control, strategic goal planning,

abstract reasoning, cognitive flexibility, and the ability to organize and adaptively use information contained in working memory.

The estimates of prevalence of intellectual deficits among offender populations as defined by IQ level vary widely; several large-scale studies have found rates similar to those in the general public. While rates of the most severe cases of cognitive impairment are low in most prison systems, few researchers would contest that rates of at least mild cognitive impairment are elevated in prison populations relative to the community. This entry provides an overview of incarcerated offenders with cognitive disorders and then focuses on evidence-based interventions. The second half of the entry explores the need for staff training and the important roles that protective factors, advocacy, and mentoring play in effective interventions.

Overview

Those involved in the criminal justice system can experience deficits that range from mild executive function problems with otherwise average or above average intelligence to more serious impairments that severely limit adaptive function. Individuals with the most severe cognitive deficits are likely to be diverted from sanctions early in the criminal justice process. Those who are incarcerated, therefore, tend to have less severe intellectual disabilities, which may make them harder to identify without the benefit of standardized assessment tools.

The origins of these neurological problems are various; for example, fetal alcohol spectrum disorder (FASD) and alcohol-related neurodevelopmental disability are conditions acquired during fetal development due to exposure to maternal drinking; various forms of mental retardation are congenital; and traumatic brain injury and organic brain syndrome are acquired through injury, disease processes, or drug and alcohol abuse. Many of the same cognitive deficits and behavior problems are shared by individuals with neurologically based disorders. The considerable overlap in the presentation of many of these conditions suggests that the treatment and case management requirements could be similar across many diagnoses.

Offenders with cognitive deficits are more likely to have comorbid mental health conditions;

in particular, rates of substance abuse disorders and personality disorders are elevated. In prison, offenders with cognitive deficits are more likely to manifest a range of problem behaviors and face a number of challenges with respect to their preparation for release. For example, rates of institutional misconducts are elevated and rates of discretionary release (i.e., earlier gradual release) tend to be lower. Offenders with the more serious forms of neuropsychological disorders have complex, lifelong problems that require adapted correctional practices and continued services on release from multiple providers.

Research Related to Offender Institutional Behavior and Reoffending Risk

The evidence base for what works for the subgroup of offenders with more serious cognitive deficits, particularly research related to reducing recidivism, is sparse. One researcher noted that the majority of research has been based on professional opinion and commentary, with few well-controlled studies and systematic reviews. There are, however, a growing number of promising practices that have proven effective with individuals with special needs (e.g., cognitive deficits) outside correctional settings that can assist offenders with special needs by improving reintegration.

Derived from this body of work, a framework for interventions with offenders with cognitive deficits, therefore, can be proposed that summarizes recommendations related to institutional correctional practices. Many of these practices are already incorporated into general correctional programs that focus on self-management skills including training on cognitive skills, such as planning, consequential thinking, problem-solving, decision-making, and emotion management skills to reduce aggression. The executive functioning problems associated with more serious cognitive deficits, such as limited working memory, inability to follow verbal instructions, and lack of retention of the sequences of daily living, can require the use of innovative intervention responses. Management of offenders with cognitive deficits requires a comprehensive strategy that begins with initial screening, and, if feasible, an enhanced assessment for those identified with deficits that would identify functional strengths and deficits, in

conjunction with a comprehensive assessment of criminogenic needs that is part of any well-developed correctional plan.

Interventions

Offenders with cognitive deficits with a substantial antisocial history are likely to manifest the same criminogenic risk factors that are typical of offender populations, but their behavior is further complicated by their neurological problems. Dynamic (i.e., changeable) criminal risk factors should be addressed in correctional programs to reduce their impact. Since the 1990s, cognitive behavioral interventions have become the preferred approach to correctional programs based on a large body of research support. For lower risk offenders with cognitive deficits and less substantial criminal histories, the focus would be on improving adaptive function in preparation for optimal independence on release. Due to the wide range and complexity of deficits among those with neuropsychological disorders, it is impossible to recommend one specific intervention. For complex and lifelong disorders, there is a need for approaches that are problem-specific, flexible, and targeted toward the individual's strengths and needs. Recognizing that there is no *one size fits all* approach to interventions for these individuals, the following general suggestions would apply to adapting group programs focused on reducing recidivism as well as to group programs that aim to improve prosocial reintegration for offenders with more serious cognitive deficits.

Adaptations and accommodations in group programs include:

- smaller group size (limited to six to eight participants);
- structured, well-organized sessions where expectations are made clear and repeated;
- close monitoring by facilitators to avoid potential interpersonal conflicts;
- teaching only one or two concepts per session;
- shortening sessions and increasing the overall length of the program;
- minimizing classroom distractions;
- repetition of material and frequent review;
- use of clear, simple, and concrete language;
- period use of multimedia learning tools (i.e., videos);

- a focus on structured problem-solving training, to a competent level of skill acquisition, without the expectation of a high level of cognitive expertise; and
- provision of one-to-one coaching sessions as an adjunct to the group program.

In addition, the correctional environment should include:

- staff training on strategies for working effectively with offenders with cognitive deficits;
- provision of continuity of care through detailed prerelease planning; and
- case management provisions that broker and coordinate specialized services such as stable housing, vocational training and job placement, and consolidation of family and/or community support on release.

For some individuals with cognitive deficits, group programs, even when adapted, may be inappropriate and ineffective. In these cases, individual therapy or adding a coaching component to programs may be more practical. Such coaching sessions would be geared toward increasing transferability of skills from the classroom to real-world functioning. Frequent practice of skills that are incorporated into daily activities in multiple settings enables individuals with neuropsychological difficulties to transfer knowledge learned from one setting to another.

Use of Medication

There is limited evidence supporting the use of psychoactive medications as a first-line treatment for individuals with serious cognitive deficits. There is, however, a substantial literature supporting use of stimulant medication with individuals with attention-deficit/hyperactivity disorder. Medical professionals caution that people with FASD have been shown to have atypical responses to medications, and the literature recommends that providers closely monitor individuals for side effects, proper administration of medication, and responses to medications. If medication is used, providing close follow-up, using low doses, monitoring side effects, and adjusting dosages rather than treating side effects are also strongly suggested.

Staff Training

Staff training to raise awareness about neuropsychological disorders in inmate populations and to suggest strategies to address challenging behavior is frequently recommended throughout the literature. Such training can help staff recognize the characteristics of offenders with neuropsychological disorders and learn to apply skills that are appropriate to an offender's level of functioning. Recommended content for such staff training sessions have been developed for FASD and traumatic brain injury that could provide helpful guidelines for developing staff training for other neuropsychological disorders as well. These guides include information on the causes and consequences of brain injury in the offender population and describe how these offenders may be affected by problems related to their deficits. They also provide management strategies for criminal justice professionals in relation to specific challenges common to those with these disorders.

Protective Factors and Promotion of Reintegration

Since 2000, correctional approaches have begun to examine protective factors that promote positive outcomes for offenders instead of uniquely focusing on risk factors. Structured leisure, employment, support of prosocial family and friends, and stable and safe accommodation are some of the best-researched factors. Case management strategies that incorporate plans to develop or strengthen these factors are likely to improve the chances for success for all offenders but may be particularly important for offenders with cognitive deficits.

Related to case management, the concept of the external brain has been widely discussed within FASD research and may be applied to others with neurological disorders. Coined by Dr. Sterling Clarren, the concept refers to the fact that individuals diagnosed with FASD have a physical impairment in brain functioning, and much like someone who has impaired vision may require a seeing eye dog or someone with impaired hearing may require a hearing aid, people with FASD require other people, external cues, and adjustments to help them function well. If there are not already services or

family systems in place to act as this external brain, case management services could help to fulfill this function by arranging for long-term services. Having a mentor or advocate to act in this capacity is ideal. Intensive or enhanced case management has been cited as a promising practice or core component of successful service models for adults with FASD and traumatic brain injury.

As parole officers function in a case management capacity in many correctional agencies, there is a growing body of literature that suggests that creating specialty parole officers with relatively small caseloads can improve outcomes for offenders with a mental illness who are on supervision in the community. Adapting this approach in working with offenders with neuropsychological disorders may be worthwhile.

Advocacy and Mentoring

Closely related to case management services are advocacy on behalf of the offender and the use of peer or other paraprofessional mentors in services for offenders with neurological disorders. An institutional advocate is someone who can work with the offender with more serious cognitive deficits to defuse interpersonal situations which can be potentially explosive and improve the offender's overall experience within the correctional system. Mentoring programs have also been identified as a promising practice for those with neurological disorders. Although in some models, case managers themselves fulfill the role of mentor, other models have specialized mentors, or peers act as mentors. Whatever the model adapted, mentoring and advocacy are both seen as an important component of services for offenders with serious deficits related to neuropsychological disorders.

COMMUNITY CONTEXT AND MASS INCARCERATION

The increase in incarceration rates from 1970 to 2010 in the United States has catalyzed research to better understand why individuals commit crimes and why they return back to prison after release (recidivate). There is clear evidence of a social concentration of incarceration among four axes: socioeconomic status, gender, age, and race. Incarceration disproportionately impacts particular segments of the general population. Those involved with the criminal justice system are overwhelmingly male, African American, younger adults, and high-school dropouts. Emerging evidence substantiates a fifth axis of concentration: place. Apart from the social and demographic trends of incarceration, there is a certain geospatial concentration of incarceration. Multiple empirical studies have determined that the majority of state correctional populations come from a handful of communities. The purpose of this entry is to demonstrate why community matters when it comes to understanding mass incarceration and its collateral consequences. The vital role of community supports is described in the form of institutional resources, social bonds, and collective citizenship.

The focus on community context is part of a larger effort to rethink the root causes of mass incarceration and its collateral consequences. Community has often been left out of discussions on incarceration. Macrosystem analysis examines

structural dynamics, such as sentencing policies, that address admissions and the length of stay in prison (considered to be the *drivers* of the prison population). Microsystem-level interventions focus on evidence-based strategies for addressing criminal behaviors, most typically upon release to community to prevent recidivism. Within an ecological framework, there is an urgent need to address a critical mesosystem-level factor: community.

Place matters. *High-stakes*, *high-incarceration*, and *high-impact areas* are rotating terms to reference localities where criminal justice responses to crime exist in concentrated levels. In some cities, these areas could be neighborhoods, while in others they might be zip codes, districts, or another geographical designation. High-stakes communities are the epicenter of state punishment outside of prisons. According to the Bureau of Justice Statistics, in 2009, 2½ times the number of people incarcerated were under community supervision (probation or parole) and concentrated in particular localities.

High-stakes communities are those with a high minority residential population, a low socioeconomic status, a high score on the hardship index, and, correspondingly, high levels of violence. Recent scholarship has demonstrated that the temporal sequence and causal dynamics of incarceration and other hardship factors are not as straightforward as presumed. The common logic one might follow is the following: High-poverty and under-resourced communities struggle with crime and violence. Subsequently, a significant percentage of residents are in contact with the criminal justice system and end up in jail or prison. New findings indicate that in high-stakes communities, crime and incarceration can have reciprocal effects; there is a bidirectional relationship. In other words, crime produces incarceration, and incarceration produces more crime. As a result of this cyclical aspect, incarceration becomes a part of the ecological dynamic of crime in particular neighborhoods.

What are potential explanations that account for this dynamic? Within these communities, a significant portion of the population is in constant flux, in and out of the correctional system, a phenomenon described as *prison migration* or *prison cycling*. High residential mobility has a deleterious

effect on community life. Mobility engenders isolation and a low degree of social integration, thus decreasing the likelihood of social cohesion and commitment to a particular locality. Prison migration is a particular form of residential mobility, in that it is forced (not voluntary) and cyclical (people are removed and then returned back to the same place). Dina Rose and Todd Clear have defined this dynamic as *coercive mobility*. Forced removal of large numbers of individuals disrupts social ties and weakens social networks. Collective efficacy, or the ability to mobilize for a common good, is thus impaired. In turn, norms of order are weakened and less able to promote prosocial behaviors rather than criminality. Scholars have explored why crime and incarceration are concentrated in a discrete set of communities. Robert Sampson's research into neighborhood crime patterns has revealed that variability in crime concentration is derived from the social and organizational qualities of those places. Additionally, high levels of incarceration exist in the same areas where there are high levels of crime as well as concentrated disadvantage. In fact, highly disadvantaged communities experienced incarceration rates 3 times higher than other communities with similar crime rates. In other words, concentrated disadvantage potentially has a greater explanatory power for concentrated incarceration than crime rates. Similarly, the results confirm that concentrated incarceration increases concentrated disadvantage, which in turn predicts higher rates of incarceration.

In explorations related to the ways concentrated mass incarceration harms communities, researchers have found that the majority of correctional populations come from a handful of urban communities. Forcibly removing large segments of the population in particular communities creates a negative ripple effect. Concentrated mass incapacitation destroys social bonds, social networks, and the capacity of community residents to respond collectively to achieve a common good. As a result, concentrated disadvantage becomes more entrenched, and deviance flourishes.

Community Supports Necessary to Repair Harm

The pathway to repairing community harm at the end of an era of mass incarceration attends to the

ecological mechanisms transmitting the impact within a community. Community supports are essential to prevent contact with the criminal justice system and to help returning citizens adapt in ways that prevent prison cycling.

Institutional Resources

Institutional resources are vital community structures with potential to improve the quality of life for all residents, to prevent crime, and to support individuals returning home from prison. Communities with strong organizations (e.g., nonprofits, religious institutions, civic groups) are able to promote prosocial norms and enhance connectivity among residents. Institutional resources improve the collective social capital of a neighborhood, which can further act as an antidote to deviance and crime. Community institutions act as agents of social integration. Following this logic, strategies that enhance the amount of local resources in high-stakes communities could effectively improve public safety and reduce the number of individuals entering into the criminal justice system. More recently, scholars have begun investigating whether or not community resources impact recidivism and reoffending. One study conducted in 2010 examined California parolees from 2005 to 2006. Findings indicated that an increase in the presence of social services (within 2 miles of a residential address) decreases the likelihood of recidivating by 41% (Hipp, Petersilia, & Turner, 2010). Community institutional supports with particular importance for returning citizens include job training and employment agencies, shelters, food banks, educational institutions, health care, and childcare.

Repairing the Social Bonds in Community

Concentrated mass incarceration substantially strains social networks in high-stakes communities. Upon reintegration, the formerly incarcerated bear a heavily stigmatized status that impairs their capacity to rebuild positive social bonds, compounded by a forced extraction and an absence from their previous networks. Community social bonds to both individuals and prosocial institutions play a major role in behavior reform and exiting criminal careers. These connections place individuals in contact with citizens engaging in

conforming activities (e.g., working, attending school). Through these social bonds, individuals develop social skills necessary to integrate into other social structures (educational institutions, workplace, religious institutions), and they gain support and social capital. Most individuals experience a reward for positive social bonding such as earning wages or obtaining a degree. These awards strengthen their social bond, which thus increases their commitment to conforming behavior.

Community supports that facilitate the reforming of social bonds are vital for returning citizens. The family unit of the formerly incarcerated is a logical target for intervention efforts. Families are the primary providers of housing and financial support for offenders after release. Families typically assist with employment, transportation, and emotional support as well. A 2004 Urban Institute Report examining the Chicago prisoner's experience of returning home indicates that programmatic interventions integrating family members and connecting them to local institutions demonstrate promising reductions in recidivism. Intervention research developed in this regard includes offender and family assessments (evaluating domains of family support and prosocial support) and different evidence-based tools to assess the quantity and quality of social bonds. These tools assist correctional staff and community supports in identifying strengths in the social network and family relationship of returning citizens.

Build Collective Citizenship in Community

Community supports that empower residents to take control of their lives and environment help to build collective efficacy. Many community-based organizations use an empowerment lens to support local leaders in identifying shared goals, mobilizing resources, and developing strategies to achieve these goals. Residential involvement in local initiatives can improve sense of control, empowerment, individual coping, and health behaviors. Community organizations may operate in a variety of ways to build social bonds and collective efficacy among residents. Community organizers often use a social action, conflict-based model. Asset-based community developers use an empowerment-oriented approach in response to community needs.

Enhancing the collective citizenship of a community can also promote collective efficacy. While the constructs of felon disenfranchisement across states vary, the majority temporarily restricts or permanently removes the right to vote for individuals with criminal backgrounds. When this occurs at a large scale in concentrated dimensions, the result is the disenfranchisement of entire communities and the erosion of collective citizenship. The political strength of the entire community is undermined when a significant portion of community members bear felony convictions. For example, S. David Mitchell demonstrated how voting restrictions inhibit the community's ability to elect representatives that serve their collective interests. The collateral consequences of felon disenfranchisement are so extensive that more attention is being drawn to a critical, yet often-overlooked aspect of reentry: civic reintegration to produce conforming (vs. deviant) citizens.

Research has found that to fully understand problems and shape solutions around mass incarceration, a community approach is necessary. This approach promotes an interdisciplinary multisector strategy for supporting individuals in contact with the criminal justice system. If actualized, community supports not only reduce the number of individuals entering prisons—they can successfully restore former inmates to full and productive citizenship.

COMMUNITY CORRECTIONS

Community corrections, or supervision, refers to programs that oversee offenders outside of jail or prison with legal authority to administer sanctions. The two most common types of supervision are *probation* and *parole*. Although probation and parole vary in how they are administered across jurisdictions, they are generally consistent in how they are defined. Probation is typically administered in lieu of a jail sentence, whereby offenders are placed under supervision in the community. Sometimes, probation is served after a short jail sentence. For example, if an offender was sentenced to 5 years with 3 years suspended, that would mean that the offender would be incarcerated for 2 years and then on probation in the community for 3 years instead of being incarcerated for all 5 years. Parole is not a stand-alone sentence but instead is served after a term in prison. Here, an offender may be released from incarceration prior to the end of the sentence (often called *discretionary parole*) or after serving all or a specified portion of the sentence (often called *mandatory parole*). Many states have abolished parole in favor of certainty in sentencing. This entry looks at the overall goals and common programs for community corrections and reviews effective supervision strategies.

Community Corrections Goals and Programs

The overall goals of community corrections are to contribute to immediate public safety (supervision of offenders) and reduce recidivism (relapse into

criminal behavior) for the long term. The majority of individuals under correctional supervision (nearly 7 million in the United States as of 2015 according to the U.S. Bureau of Justice Statistics) are not in jails and prisons; rather, they are supervised in communities, most commonly under probation or parole supervision (nearly 5 million).

Both probation and parole are terms of supervision in the community, and offenders generally serve under the supervision of a community corrections officer. The officer is responsible for ensuring that the offender does not break any additional laws while on supervision and monitors the offender's compliance with the terms of community supervision. Often, these terms include the following: maintaining steady employment, paying fees, performing community service, refraining from consuming alcohol or drugs, and avoiding associating with other offenders. Offenders who violate the terms of community supervision can be reprimanded by the supervising officer, and serious or repeated violations can result in incarceration.

There are other types of community corrections programs including jail diversion, boot camps, detention and diversion, and drug and other specialty courts. The commonality among these programs is that offenders are usually under probation supervision and are expected to complete certain programs and adhere to prescribed conditions, and if they do not, then they will receive a sentence of incarceration.

Historically, community corrections has been used as a tool to protect the community via surveillance of offenders. However, research suggests that community corrections can provide an ideal setting in which offender rehabilitation can occur.

Effective Supervision Strategies

Risk management in the community has been implemented through various strategies. Strategies such as drug testing, electronic monitoring and GPS, and effective communication support enhance supervision. However, they alone are not effective in producing long-term change once the individual is no longer being monitored or supervised. Researchers began to look more in depth at which factors needed to be addressed to specifically target recidivism. Several risk factors emerged

as clinically significant, including past criminal history, pro-criminal attitudes and antisocial behaviors, criminal thinking and cognitive distortions, criminally minded associates, substance abuse, and employment instability. Therefore, to have a long-term effect, a program must target these specific areas.

As researcher Stanton Samenow has argued since the 1970s, criminal thinking errors must be addressed through intensive programs that will equip offenders with a new set of concepts that correct lifelong patterns of criminal thoughts and actions. Researchers Jack Bush, Barry Glick, Juliana Taymans, and Michael Guevara (2011) took this research further and developed an integrated cognitive behavioral change program that addresses the offender's criminal thinking and behaviors through cognitive restructuring, social skills development, and the development of problem-solving skills. The program *Thinking for a Change* has been empirically supported and shown to reduce recidivism.

D. A. Andrews (2011) proposed a method of assessing offenders' risks and needs: the Risk-Need-Responsivity model. The basis of the model is that offenders are less likely to recidivate when programs target the level of risk for recidivism (Risk principle), target their criminogenic needs (Need principle), and match the treatment with their skills (Responsivity principle). With the resurgence of opioid addiction and attention to the number of overdose deaths, there has been an increased focus on substance abuse treatment needs combined with cognitive treatment. New programs and community supervision alternatives such as drug courts are being implemented. No matter what issues an offender may present, it is imperative to continue to provide evidence-based treatment and program alternatives to incarceration that offer meaningful supervision for offenders while maintaining the safety of the community.

COMMUNITY NOTIFICATION POLICIES

Community notification policies seek to prevent crime, raise awareness, or otherwise educate the public about criminal activity by requiring or permitting the police or other community actors to disseminate information to the public. Policies can focus on potential victims, potential offenders, the community at large, or some combination of these three. Victim-oriented policies seek to reduce the likelihood of victimization by encouraging precautionary behavior on the part of at-risk individuals. Offender-oriented policies publicize information (e.g., the severity of penalties or the likelihood of arrest) with the aim of deterring potential offenders from engaging in harmful activities. Community-oriented policies provide the public with information in hopes of increasing cooperation and communication with law enforcement. Policies are usually oriented toward more than one audience. To be effective at reducing criminal activity or its costs, community notification information must reach its target audience and its content must be clear, salient, and capable of altering behavior. Community notification policies also carry risks of unintentionally exacerbating criminal activity. On the whole, relatively little rigorous evidence exists on the consequences of these policies.

Victim-Oriented Notification Policies

Victim-oriented community notification policies—the largest category of community notification policies in number and importance—fall into two primary categories: criminal offender registries and criminal activity communications. The former is typified by public sex offender registries. Public registries generally require certain types of released criminal offenders to provide current contact and other information to law enforcement authorities and permit or mandate that these authorities disclose this identifying information, along with offender criminal history information, to the public. The latter includes various communications (e.g., fliers, e-mails, or other electronic or media announcements) about specific crimes in addition to aggregated distributions of crime-related activity information, often in the form of crime-related statistics or criminal *hot spot* maps.

Public Registries of Offenders

Publicly available offender registries have a long history in the United States, but the modern form came of age in the 1990s at the state and federal levels through enactments pursuing the reduction of sex offender recidivism. In theory, enactments of this type could require the publication of identifying information about *any* convicted offender (or even any individual determined by the public to be *dangerous*), but, in practice, these postrelease laws apply, with a few exceptions, to convicted sex offenders.

To become subject to such requirements, an individual must be convicted of a *covered* offense specified by statute. If covered, the offender must supply identifying information—for example, name, date of birth, addresses, and photograph—at regular intervals to designated officials or agencies. This information is or can be made public. Publication can occur in several ways, but the best known outlets are the so-called web registries, which allow members of the public to search for released offenders with particular characteristics (e.g., living near a particular address) or to locate specific individuals previously convicted of sex crimes.

These laws are typically justified on two grounds. First, proponents claim that public registration policies empower would-be victims against recidivism by ensuring that at-risk individuals have

access to potentially critical information that will allow them to protect themselves and otherwise engage in effective precautionary behavior. Second, supporters assert that the public identification of potential recidivists effectively serves to deputize the public, providing more intensive monitoring of potential recidivists than would otherwise be possible. This scrutiny, they claim, can deter criminal behavior as well as facilitate apprehension and conviction. A third potential benefit of these laws might be the deterrence of would-be offenders by threatening an alternative sanction in the form of publicity, and therefore notoriety and shame, for the commission of a covered offense.

Critics of these laws question whether the public actually uses community notification information to engage in effective precautionary behavior and whether the plausibly criminogenic collateral consequences associated with publicly identifying released offenders might not exacerbate recidivism. In the case of public sex offender registries, a large fraction of the public does in fact access information about registered offenders, and sex offender registries are well-known and salient sources of information. Evidence that users of these registries engage in genuine precautionary behavior, however, is limited. Moreover, existing social science research indicates that the collateral consequences of being *known* publicly as a sex offender are significant (e.g., fewer employment and housing opportunities), that public registration laws may exacerbate other known recidivism risk factors, and therefore that these laws may not only be ineffective but also be counterproductive.

Several states and other jurisdictions have considered or adopted the public registration of other categories of convicted felony offenders. Examples include registries of a broad range of violent, white collar, methamphetamine, domestic violence, animal abuse, hate crime, elder abuse offenders, among others. Defenders of these registries have cited grounds identical to those used in support of sex offender registries, despite several potentially important differences in the underlying criminal activity at issue. For instance, offenders engaged in market-oriented crimes—like selling drugs—might actually benefit from the availability of publicly provided lists of potential producers, distributors, consumers, or coconspirators. Another difference relates to the potential number

of covered offenders. While public sex offender registries are certainly not small, a comprehensive violent offender registry would carry an even greater risk of overwhelming potential victims with so many names and details that its users may be unable to employ the registry's information in socially productive ways.

Despite little evidence that publicly registering offenders reduces recidivism, this category of community notification policy continues to be attractive to policy makers and popular among the broader public. Scholars have rooted this disconnect in the intuitive nature of these policies, in the disgust that the public feels for certain categories of these offenders (e.g., sex offenders), and in basic psychology. Registries may make people feel safer by providing an increased sense of control over sources of risk that seem most threatening to them. People worry most about risks that are unfamiliar and difficult to control, regardless of whether the true level of risk is significant. Crime victimization risk is associated with an acute sense of loss of control that motivates individuals to take steps to regain control over their circumstances. Information seeking is one potential strategy; it is psychologically gratifying even if, objectively, acquiring the knowledge does little to reduce actual risk.

Criminal Activity Communications

Criminal activity communication policies and practices support the distribution of information to the public regarding ongoing or recent criminal activity. The goals of such communications are two-fold. First, fresh information on recent criminal activity—especially at the aggregate level—can warn potential victims of existing risks about which they may have been unaware. Such communications allow citizens to take greater care by avoiding particular locations or taking other precautions. Second, broadly sharing information on criminal activity—particularly at the level of individual incidents—may encourage citizens who have witnessed crimes to report what they know or otherwise assist law enforcement in apprehending perpetrators. Although making the extent and scope of criminal activity public knowledge may have downsides from a policy perspective (e.g., engendering unnecessary or unproductive public

fear or inciting *copycat* criminals), the claimed upsides are that citizens will be better able to protect themselves from criminal victimization and that law enforcement activities will be more accurate and efficient in solving cases and ultimately reducing crime.

Community crime alerts may take the form of fliers, listserv e-mails, or media announcements. These alerts often include a vague description of the suspect, a summary of the alleged crime, and, importantly, the location where the incident is believed to have occurred. Typical crimes covered by these alerts include burglaries, robberies, assaults, rapes, and murders. With these alerts, there is always a chance that someone might help law enforcement apprehend the right suspect on the basis of the vague description alone, but the likelihood of this occurring is often thought to be low. Instead, the primary purpose of many of these alerts (and alert policies) appears to be simply to raise awareness of the extent and nature of victimization risk at particular places and times and hopefully prevent future crimes.

Some crime alert policies, however, specifically focus on bringing an ongoing crime to an end. Consider the design and goals of the well-known America's Missing: Broadcast Emergency Response Alert System, which comprises a set of community crime alert policies that extend across the country. Under this system, if law enforcement officials conclude that a child has been abducted and all other America's Missing: Broadcast Emergency Response Alert criteria are satisfied (e.g., risk of serious bodily injury or death, sufficient descriptive information on the victim, and a 17-year-old or younger victim), law enforcement will notify the media and transportation officials of the details of the abduction, which are then disseminated over radio, television, highway signs, etc. These alerts are often rebroadcast by other organizations, including Internet search engines and mobile phone companies. The America's Missing: Broadcast Emergency Response Alert System may be atypical, however, in that its principal goal is to facilitate the recovery of an abducted child.

With the rise of social media and other online forms of communication, criminal activity alerts have become integrated into social media networks. Thousands of law enforcement agencies have social media accounts; while there are

drawbacks to using social media (including the potential for selective and misleading redistribution of particular crime alerts by the public), there are likely to be significant advantages, too. One benefit is that police departments no longer have to work through the media via press releases to issue crime alerts. Law enforcement agencies can theoretically provide accurate, timely, and balanced information on criminal activity and can do so as often as they believe appropriate. Another benefit may arise from the fact that social networks are multidirectional communication platforms and so the public will be able to identify errors in and report confusion about particular crime alerts, which law enforcement agencies can then correct. Finally, because social networks may enhance the quantity and quality of communication from members of the public to law enforcement agencies, the chances that alerts will lead to actionable tips may increase.

At a more general level, social media technology allows law enforcement to engage in open dialogue with the communities they serve in an instantaneous, networked manner and thus may work to improve community-police relations. Where this possibility exists, current policies and practices involving criminal activity notification have the potential to morph into an extension of community policing. An example of this dynamic can be found in the Boston Police Department's successful use of Twitter during the Boston Marathon bombing investigation in 2013 to keep the public up to date on the status of the criminal investigation, to seek community tips and offer support to those affected or concerned, and even to correct false or misleading information being reported by mainstream media outlets.

Criminal activity communications also include law enforcement releases of aggregate crime data or crime maps, both of which seek to give a more complete picture to members of the public of the state of criminal activity in their community over a period of time. Sharing information in this form is unlikely to result in the apprehension of a particular criminal or in solving a particular crime on the basis of a citizen tip. Instead, the goal is to reduce crime by encouraging the public to be aware of particular crimes in particular places at particular times. Crime mapping is especially increasing in popularity, although as a practical

matter, detailed criminal activity maps (relative to direct crime alerts) seem much less likely to reach citizens and affect their behavior in ways that reduce their risk of victimization.

Criminal activity communications also raise a number of significant concerns. For instance, community notification practices may reinforce negative racial stereotypes. Importantly, scholars have found evidence indicating that individuals are more likely to have implicit and explicit biases toward Black people after reading a crime alert describing a Black suspect. Black suspects appear to be overrepresented in crime alerts, and evidence suggests that this overrepresentation is correlated with negative stereotypes about Black people as a group. Another challenge is the government's lack of control over the dissemination of a message once it is released, for example, over social media or by e-mail. A bystander's selective further dissemination or manipulation of this information has the potential to cause significant harm. On the other hand, community notification may serve to correct rumors and misinformation. The public can also put criminal activity information to ill-use. Alerts that identify a particular offender, public offender registries, or even crime maps can enable vigilantism. Finally, policies that circulate aggregate statistics and crime maps must rely on consumers of these resources to understand the limitations of such analysis and of the underlying data. Mapping, in particular, may stigmatize certain neighborhoods as *high crime* when data are presented without appropriate caveats, leading to consequences that can negatively affect communities.

Offender-Oriented Notification Policies

Offender-oriented notification policies seek to reduce criminal activity by conveying information directly to potential offenders in order to affect their decision-making regarding potentially harmful or criminal behavior. Examples include the broadcast communication of law enforcement tactics, techniques, and crackdowns; the scope of penalties for certain criminal conduct; and recent changes in criminal law. The underlying assumption of these policies is that potential offenders are aware of and will react to changes in their legal environment. In a traditional economic model of

crime, law enforcement activities are assumed to affect the likelihood of conviction and/or the severity of punishment. Notification policies, by contrast, offer the potential to shape an offender's *perception* or estimation of both of these parameters. Offender-oriented notification policies also seek to influence an offender's evaluation of any nonlegal consequences of crime. Examples include a victim's suffering or the disgrace and embarrassment an arrest or conviction causes an offender's friends and family.

Media campaigns against drunk driving may be the most well-known examples of offender-oriented notification policies. These public service announcements concentrate almost exclusively on deterring potential offenders; they rarely seek to educate potential victims about how they can best protect themselves when in close proximity to a drunk driver. Admittedly, these policies are community oriented in that they sometimes encourage third parties to intervene with potential offenders prior to the commission of crimes—for example, “Friends don’t let friends drive drunk.” But generally, these policies impart the message to potential offenders that drinking and driving carries with it a high likelihood of apprehension by law enforcement as well as harsh penalties upon conviction. These policies also seek to shame those who drink and drive by associating their behavior with wrongful risk-taking, highlighting in a more tangible way the potential for terrible harm to victims and their families. Notably, evidence on the effectiveness of these sorts of campaigns is mixed.

Community-Oriented Notification Policies

Community-oriented notification policies seek to educate members of a community broadly about crime, law enforcement, and the law. The goal is to empower citizens to reduce crime directly through their own activities (e.g., monitoring) and by cooperating with law enforcement (e.g., reporting). Community-oriented policies also affect potential victims and offenders but differ in that they communicate information to and affect the behavior of individuals who realistically do not fall into either of these categories. In this sense, public registries of offenders are both victim oriented and community oriented. Not only are potential victims encouraged to engage in

precautionary behavior, but other members of the community are given tools to monitor potential recidivists and to report suspicious behavior to law enforcement. Likewise, offender-oriented notification practices like drunk-driving campaigns may also encourage third parties (e.g., bartenders and friends) to intervene and prevent crime. Community-oriented notification policies also seek to educate the public about risky activities that may produce harm and abet criminality (e.g., drug use) and to instruct citizens on how best to work with law enforcement or emergency responders to reduce harm, to interrupt criminal activity, or to facilitate the capture of offenders (e.g., 911 emergency number information campaigns and “See Something, Say Something” terrorist activity prevention campaigns).

A classic example of a community-oriented notification policy is the decades-old “Take a Bite Out of Crime” campaign. The first phase of this campaign was more victim oriented; it offered audiences tips about protecting their homes and other property. But the second and third phases emphasized observing and reporting suspicious activity and pushed neighborhoods to organize and carry out crime-prevention strategies. As in the criminal activity communications context, the future of community-oriented notification practices may be found in the use of social media tools by law enforcement. Social media platforms ease communication with the public. Electronic messaging can keep the public up to date on investigations and encourage community members to report relevant information in a timely manner. Moreover, the two-way nature and speed of social media technology may humanize and legitimize the police in much the way community policing has been said to improve community-law enforcement relations. The result might well be a greater willingness of some communities to cooperate with police.

Concluding Thoughts

The behavioral consequences of community notification policies are generally undertheorized and understudied. To be successful, notifications relating to criminal activity must be received, salient, and consistent with existing beliefs. Policies that provide specific information are often claimed to be more successful, but message salience varies among subgroups, and so specificity may be

immaterial under many circumstances. In some contexts, but not others, notification appears to influence perceptions of crime and victimization risk, beliefs about appropriate responses, and whether individuals engage in precautionary or monitoring behavior. This lack of consistency suggests that the specifics of the policy or practice and the criminal context are critical to accurately predicting the behavioral consequences of community notification policies.

COMMUNITY POLICING AND CRISIS INTERVENTION TEAM MODEL

Community policing is defined as the establishment and use of partnerships and problem-solving techniques to address public safety concerns, such as the rise of crime in a particular geographic area. Over the decades, policing in the United States has changed from a two-pronged system with a volunteer patrol and a pay-per-warrant force to a unified police force. By the 1880s, all states had a unified police force, with the primary goal of disorder control rather than preventing an increase in crime. Throughout the history of policing in the United States, the role of police officers, in its fundamental form, has remained the same: protect their community. However, how this is done today looks very different than it did in the 1880s.

Since the 1950s and 1960s, due to a variety of reasons—such as Social Security and other governmental benefits, advances in treatments, a greater awareness of the substandard conditions of state psychiatric hospitals, and the emerging civil rights movement—deinstitutionalization of individuals with serious mental illnesses began to occur. However, many communities lacked the social services to assist those with mental health concerns. As a result, modern police forces often are called upon to interact with and assist persons with serious mental illnesses, despite having little training.

This entry focuses on community policing and the Crisis Intervention Team (CIT) model, a model that the CIT International organization defines as a specialized police-based crisis response model, integrating community, mental health care, and mental health advocacy groups. The training that CIT provides (which can be started independently by any

agency) gives law enforcement and other first responders the knowledge and skills to respond to calls involving persons with mental illnesses, while maintaining the safety of all parties involved. This training strives to reduce stigma and keep persons with mental illnesses out of the justice system when possible, coupled with innovative problem-solving and program development.

Community Policing Overview

According to the U.S. Department of Justice, community policing is built upon three components: community partnerships, organizational transformation, and problem-solving. *Community partnerships* may involve other government institutions, local nonprofit organizations, community businesses, and the media. *Organizational transformation* refers to the administrative aspect, such as agency management (e.g., culture, leadership), organizational structure (e.g., geographic placement of law enforcement officers), personnel (e.g., hiring practices), and information systems (e.g., communications, data access and use). *Problem-solving* follows the acronym SARA: scanning (e.g., identifying problems), analysis (e.g., research), response (e.g., long-lasting solution development), and assessment (e.g., evaluation of the response).

One model that was initially hailed as the gold standard of policing, and may have served as a predecessor to community policing, is known as the *broken windows theory*. A criminological theory first detailed in 1982 by James Q. Wilson and George L. Kelling, the broken windows theory suggested that law enforcement focus on lesser or misdemeanor crimes (e.g., broken windows) as a way to prevent more serious crimes (e.g., homicide). As a result, communities would feel comfortable, safe, and empowered, thereby reducing the amount of criminal activity.

Broken windows was introduced in New York City by Rudy Giuliani, who took office as mayor in 1993, and his police commissioner, William Bratton. Very quickly, the city saw a sharp decrease in criminal activity, and broken windows was hailed by some as a miracle. However, skepticism also arose. Columbia Law School professor Bernard Harcourt noticed that crime was decreasing not only in New York City but also across the entire country where broken windows was *not* implemented. Moreover, crime decreased in cities with rampant police

corruption, such as Los Angeles. In an attempt to explain why broken windows was not as effective as it seemed, Harcourt referred to regression to the mean; in other words, what goes up must come down. Before the sharp downtick in criminal activity was a pattern of upticks and downticks in the same behavior. While Kelling acknowledges broken windows may not be the miracle everyone was looking for, he claims it still has value, stating that any reduction in crime is positive.

Broken windows was followed by another policing technique known as *stop and frisk*, whereby officers pull over or stop civilians and search them for weapons or other illegal items. After taking office as New York's new mayor in 2001, Michael Bloomberg wanted to take broken windows one step further and prevent crime before it even happened, leading to the use of stop and frisk by New York City police officers. Of the 250,000 stops made by the New York City Police Department in 2008, only one fifteenth of 1% revealed a gun. Moreover, because African American citizens were the ones in neighborhoods with more physical broken windows, loitering, and graffiti, arrests of African Americans increased. In 2013, a federal district court ruled stop and frisk unconstitutional, and then-Mayor Bill DeBlasio officially ended the practice but reinstated both broken windows and Giuliani's police commissioner Bill Bratton.

Despite evidence showing broken windows does not work, Harcourt says it maintains popularity because it is an easy idea for the public and the government to understand. The balance of the popular versus the scientific is critical when discussing how police interact with persons with mental illnesses. In that regard, it is important to include CIT in a discussion of community policing, as the issue of how to resolve situations involving persons with mental illnesses and relationships between law enforcement and the mental health community involves systematic partnerships and collaboration in the same way that community policing does.

The Impact of Serious Mental Illnesses on Policing

To understand the role of CIT in the law enforcement community and in society at large, how

mental illnesses factor into daily policing efforts needs to be understood. Mental health concerns are not isolated from the law enforcement community. According to the National Institute of Mental Health, approximately one in five adults (43.8 million or 18.5%) experience a mental illness in any given year, with one in 25 adults (10 million or 4.2%) experiencing a serious mental illness that impairs daily functioning. Many individuals with mental health concerns also abuse substances, making the job more challenging for the responding officer. Issues arise as to the legality of the person's actions: Is the person committing a crime, or is he or she acting due to the symptoms of a psychological condition? Because law enforcement officers are trained to recognize crime rather than psychological distress, the effects of the mental health condition may go unrecognized or be downgraded in favor of immediate community safety. The outcomes of such a decision may end well, but they are just as likely to end poorly.

Many police officers cite interactions with persons with mental illnesses as a significant concern. Estimates of police interactions with persons with mental illnesses range from 7% to 49% of all encounters. Feelings of preparedness among officers and their colleagues tend to be mixed, with about a 50/50 split of each according to one published study. International research documents the problem, with one major study conducted by the Mental Health Commission of Canada finding that persons with mental illnesses had 3.1 times more interactions with police compared to the general public, were twice as likely to be reinvolved with the police compared to the general public (79.9% vs. 38.3%), and were more likely to be convicted of an offense compared to a member of the general public who committed the same offense but does not have a mental illness (72% vs. 60%). As such, many persons with mental illness tend to be housed in the justice system rather than receiving proper psychiatric care, with a 2006 special report by the Bureau of Justice Statistics estimating a total of 705,600 persons with mental illnesses housed in state prisons, 78,800 in federal prisons, and 479,000 in local jails.

Despite recent media reports and cellphone videos posted online to video-sharing sites such

as YouTube, interactions between police and persons with mental illnesses rarely lead to fatalities. Nonetheless, use of force tends to be more frequent against persons with mental illnesses compared to members of the general public. Despite mental health–related legislation and policies in every U.S. state and Canadian province, police frequently report feeling trapped regarding how to handle the situation due to their own stress, lack of resources such as hospital beds, and pressure from supervisors to move on to the next call. As a result, police tend to express frustrations with the mental health system, and the mental health system tends to feel frustrated with law enforcement. Thus, specialized training and forms of collaboration, such as CIT, have been developed.

CIT Model

Development

CIT, also known as the *Memphis Model*, was developed in Memphis, TN, in 1988, after law enforcement officers fatally shot an individual with a mental illness. Since its inception, CIT has been implemented in multiple jurisdictions in nearly all states in the United States, with Canada, Australia, and New Zealand using similar models (e.g., Toronto’s Mental CIT that pairs a trained law enforcement officer with a registered nurse; New South Wales’ Mental Health Intervention Team).

Core Elements

CIT International divides the core elements of CIT into three types: ongoing, operational, and sustaining. *Ongoing elements* constitute partnerships between law enforcement, advocacy groups (e.g., National Alliance on Mental Illness, Mental Health America), and mental health services and organizations. *Operational elements* are the roles of officers, dispatchers, and coordinators; curriculum development; and mental health facilities, such as emergency services. Finally, *sustaining elements* include evaluation and research, in-service training, recognition and honors, and outreach (developing CIT in other communities; local, regional, and statewide implementation; and legislative change).

Curriculum

CIT International states that a successful implementation of the training for most jurisdictions will have trained approximately 20–25% of the agency’s patrol division, with consideration of various factors such as agency location, size, and resource access. CIT officers typically volunteer for the 40-hr comprehensive training. CIT programs often divide their training into five activities: (1) didactics and lectures to convey specialized knowledge (e.g., clinical issues, medications, co-occurring disorders, suicide prevention), (2) on-site visits and exposure to persons with mental illnesses who are in successful treatment and recovery, (3) practical skill development through scenario-based training, (4) questions and answers, and (5) commencement and recognition. Dispatchers are also encouraged to receive some version of CIT training. Their curriculum is comprised of four elements: (1) recognition and assessment of a crisis event, (2) appropriate questions to ask a caller, (3) how to identify the nearest CIT officer, and (4) policies and procedures. While an approved CIT curriculum needs to adhere to these components, each community develops its curriculum based on local needs, political climate, and access to resources, among other factors.

Use of Force

Of great importance to police and persons with mental illnesses is *use of force*, that is, how much force is being used against a person with a mental illness by law enforcement to resolve the situation. While they still use force when appropriate, CIT-trained officers appear to use less force compared to their non-CIT-trained counterparts to resolve the same or similar calls, relying on other techniques such as verbal de-escalation.

Handcuffs are one use-of-force tool that is controversial within the mental health community. Many mental health advocates state that they should be avoided because they add to the embarrassment and perceived injustice of the individual. Moreover, handcuffs can make the individual feel like a criminal, even though mental health concerns are not a criminal act. Seeing a person with mental illness in handcuffs runs counter to efforts to dissociate mental health problems from criminal activity. However, law enforcement officers

are often instructed to exercise discretion, thereby allowing them to decide when handcuffs should be used. The ideal goal is to use them only when the individual is combative and jeopardizes his or her own safety or the officer's or others' safety.

CIT training educates officers as to when a situation may call for the use of an assistive device (e.g., handcuffs), while allowing officers to escort the individual to a hospital or other mental health services, either via patrol car or ambulance. The implementation of state or provincial mental health law-related policies also allows officers to take the person into custody for their own safety. CIT training teaches officers how to build relationships with their local hospitals and mental health facilities, while also educating them on what social services are available.

Empirical Evidence

CIT has been relatively extensively researched compared to other policing programs. To date, nearly all research in books and academic journals has focused on officer-level outcomes, that is, effectiveness of CIT training on improving their attitudes, knowledge, skills, and daily interactions with persons with mental illnesses. The majority of CIT research has demonstrated its effectiveness in allowing officers to recognize mental illnesses in others. CIT training may also be effective in allowing officers to recognize symptoms of mental illness in themselves (e.g., depression, anxiety, post-traumatic stress disorder, substance abuse) and to better understand what they are experiencing and thus seek the proper resources for treatment when needed. Moreover, CIT training helps officers to feel more confident in their department as well as in themselves to handle calls involving persons with mental illnesses. Finally, while CIT training can be expensive, it is cost-efficient in the long term. For example, a 2014 study found that the implementation of training in a medium-sized city cost USD \$2,430,128, with annual savings post-training of USD \$3,455,025.

COMPETENCY FOR EXECUTION

Competency for execution refers to a person's ability to understand the reason, imminence, and finality of his or her execution. The evaluation of

competency for execution is one of the most infrequently encountered, but arguably highest stakes, of forensic mental health evaluations. Because an evaluation of competency for execution is inextricably and proximally associated with the carrying out of a death sentence, the participation of mental health experts in such determinations has been the subject of ethical controversy in the professional community. This entry reviews the conceptual framework of contemporary parameters of competency for execution in the United States and discusses challenges associated with competency for execution evaluations.

Conceptual Framework

Prohibiting the execution of mentally incompetent persons is a centuries-old social and religious value, embedded in English common law and subsequently early American jurisprudence. According to this value, executing a person who is so deranged as to not understand the reason, imminence, and finality of the execution robs the sanction of social dignity, meaningful retribution, and general deterrence, and deprives the person the opportunity to make peace with his Maker (e.g., repentance). In modern U.S. jurisprudence, two U.S. Supreme Court decisions have fundamentally framed and structured the conceptual parameters of competency for execution.

Ford v. Wainwright (1986)

Alvin Bernard Ford was convicted of capital murder and sentenced to death in 1974 for killing a police officer. Ford began to exhibit symptoms of schizophrenia several years after his trial. By 1982, he was experiencing paranoid and grandiose delusions, referring to himself as Pope John Paul III and asserting that he had appointed nine new justices to the Florida Supreme Court. The *Ford* Court ruled that execution of an “insane” person was prohibited as “cruel and unusual punishment” under the Eighth Amendment to the U.S. Constitution. The Court cited rationales from English common law precedents, but the ruling provided no operational definition or procedural prescription for determining competency for execution, beyond adequate due process, which Ford had not been afforded.

Justice Powell, in a concurring opinion, offered greater specificity. Also reasoning from common law

precedents, Justice Powell cited a number of rationales against the execution of the insane: (1) preserving the defendant’s “ability to make arguments on his own behalf” that might stay the execution, (2) the execution of a “mad man” would be a “miserable spectacle,” (3) an execution in such a context “can be no example to others,” (4) the defendant would be sent into another world when he did not have “the capacity to fit himself for it,” that is, “most men and women value the opportunity to prepare mentally and spiritually, for their death,” and (5) the retributive goal of execution depends on the defendant’s awareness of the penalty’s existence and purpose. The concurring opinion concluded:

If the defendant perceives the connection between his crime and his punishment, the retributive goal of the criminal law is satisfied. And only if the defendant is aware that his death is approaching can he prepare himself for his passing. Accordingly, I would hold that the Eighth Amendment forbids the execution only of those who are unaware of the punishment they are about to suffer and why they are to suffer it.

Distilled, three elements of competency for execution are prescribed by Justice Powell. The defendant must be aware (1) that he is to be executed, (2) that his execution is imminent, and (3) the reason for his execution. Regarding the defendant’s ability to aid and assist in his own defense, Justice Powell found no constitutional requirement but offered that states were free to take a more “expansive view of sanity” than what he specified as the “constitutional minimum” under the Eighth Amendment. The competency for execution test as prescribed by Justice Powell in *Ford v. Wainwright* was generally interpreted to require only a factual, as opposed to rational, understanding of the three aforementioned essential elements.

Panetti v. Quarterman (2007)

In 1992, Scott Louis Panetti murdered the parents of his estranged wife. Panetti had a 10-year history of mental illness and psychiatric hospitalizations prior to this offense. At trial, Panetti, who represented himself, dressed in a Tom Mix cowboy outfit and attempted to subpoena John F. Kennedy, Jesus Christ, and Pope John Paul II. He was convicted of two counts of capital murder and sentenced to death.

As his execution date approached in 2004, Panetti's appellate counsel raised his competence for execution. Panetti understood that the state of Texas *said* it wanted to execute him for murder. However, he had a delusion that the stated reason was a sham that the actual purpose of the execution was to prevent him from preaching the gospel.

In *Panetti*, the Court expanded the legal standard for competency for execution. The majority reasoned that both the individual and social retributive value of execution required that the condemned not only have a factual awareness of the state's rationale for the execution but also a rational understanding of this.

Evaluation of Competency for Execution

As mentioned earlier, the evaluation of competency for execution is a high-stakes forensic mental health evaluation. Some of the controversy and challenges surrounding competency for evaluations is due to jurisdictional and U.S. Supreme Court ambiguity regarding the specific abilities that constitute competency for execution, sparse research on competency for execution evaluations, inconsistency in prevailing evaluation procedures, and limited forensic instruments for assessing competency for execution.

Acknowledging these challenges, the gravity of the determination creates a professional obligation for competency for execution evaluations to be objective, conceptually informed, well memorialized, multisourced, and broad in focus. The following 10 recommendations, distilled from the scholarly literature on competency for execution, promote these goals:

1. *Objectivity.* Evaluations of competency for execution require a strong commitment to objectivity and an absence of bias regarding the death penalty or its imposition.

2. *Knowledge.* Competency for execution evaluators should be familiar with the *Ford* and *Panetti* decisions, the case law and legal criteria for competency for execution in the relevant jurisdiction, and scholarly literature regarding competency for execution.

3. *Scope.* Competency for execution evaluators should consider competency in the broadest terms (e.g., factual awareness, rational understanding, and capacity to aid and assist), leaving to the

courts to determine what is applicable. Notably, the competency for execution evaluators in *Panetti* addressed deficits in his rational understandings, though only factual awareness appeared to be required under *Ford* and the statute.

4. *Complexity.* Operationalizing the inquiry to illuminate the continuum of competency purposes discussed in *Ford* (e.g., mentally and spiritually prepare for death) is not a simplistic endeavor. Competency for execution evaluators should explore and describe nuances in the defendant's understandings and capacity. Competency for execution evaluators may find that utilizing competency for execution checklists and rating scales from the scholarly literature facilitate this effort.

5. *Response style.* The assessment should include consideration of whether the defendant is feigning or exaggerating symptoms of psychological disorder or cognitive deficiency. Instruments such as the Structured Interview of Reported Symptoms, first and second editions and the Miller Forensic Assessment of Symptoms Test address the former, while instruments such as the Test of Memory Malingering and the Validity Indicator Profile illuminate the latter.

6. *Notice.* As with all forensic mental health evaluations, the competency for execution evaluator should advise the defendant of the nature and purpose of the evaluation, who retained the evaluator, the distribution of the evaluation data and findings, and the possible outcomes from the evaluation.

7. *Multiple interviews.* Psychological disorders may vary in symptom severity and associated rationality. For this reason, the competency for execution evaluator should interview the defendant on more than one occasion. It may also be helpful for the evaluator to inspect the defendant's cell and observe the defendant's behaviors in his or her death row cell.

8. *Multiple sources:* The evaluation should include multiple data sources. Contemporaneous collateral observers should be interviewed, including line and medical correctional staff, other death row inmates, chaplains, appellate counsel, and persons having had recent visitation or phone interactions with the defendant. Observation of the interaction between the defendant and his appellate counsel should also be considered.

Recent and historical death row logs and mental health records should be reviewed. If available, copies of recent correspondence as well as recordings of recent phone and/or visitation conversations should also be reviewed. Some scholars recommend personality and intellectual testing in evaluating competency for execution, while others conclude that such testing is too detached from functional capabilities to inform the issue.

9. *Memorialized*. The evaluation should be well memorialized so that other evaluators, attorneys, and the courts can scrutinize the parameters of the inquiry and the defendant's responses.

10. *Descriptive report*. The report of the competency for execution evaluation should include detailed descriptions of sources and information as well as transparency in how this information was synthesized and analyzed. The descriptive illumination, as opposed to conclusion, is likely to be most helpful in educating and facilitating the determination of the court.

incompetent to stand trial. The incompetency doctrine attempts to ensure that all defendants have an opportunity to be mentally present and to participate in their own defense, thereby upholding the dignity and reliability of court proceedings and assuaging the public's confidence in the fairness of the criminal justice system. Although *competency to stand trial* is a legal term, it comprises several psycholegal abilities, which are evaluated by psychologists and other mental health professionals. The evaluations conducted by these professionals form the basis for an opinion regarding the defendant-in-question's psycholegal capacities. Defendants found to be incompetent to stand trial have their proceedings postponed until they have been restored to competency at which point the legal proceedings typically resume.

Background

With an estimated 60,000 evaluations conducted each year in the United States, competency to stand trial is a commonly conducted psychological evaluation for the criminal justice system. In general, competency to stand trial pertains to a defendant's ability to understand the charges against him or her and the general legal process, requiring the defendant to have the ability to understand and function in that context in order to assist with his or her case. It is important to understand that competency to stand trial involves the evaluation of a defendant's current mental functioning and not mental functioning at the time of the offense (this is referred to as *criminal responsibility or insanity* and is a different issue from that of competence). The issue of competency can be raised at any point during trial before a verdict is rendered. Typically, a mental health professional conducts the competency evaluation, and depending upon jurisdictional protocols, more than one evaluator may be involved. Competency to stand trial falls under the larger umbrella term of *adjudicative competency*, which encompasses several distinct criminal competencies (e.g., competency to waive *Miranda* rights, competency to plead guilty, and competency to be sentenced). The constitutional minimum standard for each of these distinct criminal competencies was set out in *Dusky v. United States* (1960) and elaborated in *Godinez v. Moran* (1993).

COMPETENCY TO STAND TRIAL

The issue of competency to stand trial refers to a defendant's current mental functioning at the time of his or her trial: Those who are unable to understand the court proceedings or unable to assist counsel in their defense as a result of mental disorder or cognitive deficit are considered

Legal Standard

The legal standard for competency to stand trial was established in *Dusky v. United States* (1960), where it was held that in order to be deemed competent, a defendant must have “sufficient present ability to consult with his lawyer with a reasonable degree of rational understanding” and a “rational as well as factual understanding of the proceedings against him” (p. 402). In other words, a rational understanding means that the defendant must be able to understand the charges and the trial process in relation to himself or herself as the defendant. A factual understanding means that the defendant must have knowledge about the people and proceedings relevant to a trial. Since *Dusky* was established in 1960, each state has adopted some variation of this standard.

All civil and criminal defendants are presumed to be competent; therefore, if competency is a concern, it must be formally raised. The question of competency can be raised either by legal party or by the court, though most often it is raised by the defense. To warrant a competency to stand trial evaluation, a bona fide doubt must exist, representing a fairly low legal threshold and making it relatively easy to request an evaluation, likely contributing to the high frequency of these assessments. Evaluations of competence to stand trial are conducted on either an inpatient basis or an outpatient basis, with many states moving toward a least restrictive setting protocol for competency evaluation. In addition, jail-based competency evaluations are increasing in frequency as more states implement strategies to reduce the wait-list for these evaluations. Each state has its own statutes and procedures for how these evaluations are to be conducted, by whom, and within what time frames.

Evaluation of Competency to Stand Trial

A qualified mental health professional may perform a competency to stand trial evaluation. Generally, the evaluating professional must establish the presence or absence of a mental disease or defect that impairs the defendant’s current mental functioning as it affects his or her ability to meet criteria for competency to stand trial in the respective jurisdiction. Several forensic assessment instruments exist to assist evaluators in formulating

their opinions regarding competency. Among the more recent are the Fitness Interview Test–Revised, the MacArthur Competence Assessment Tool–Criminal Adjudication, and the Evaluation of Competency to Stand Trial–Revised. Using data from interview and forensic assessment instruments, the evaluator must then come to an opinion about the degree to which the defendant is impaired with respect to the abilities required to proceed. The characteristics of the defendant and the context of his or her case must be taken into consideration in arriving at an opinion regarding a defendant’s competence. Evaluations are typically conducted with a focus on functional abilities, that is, extrapolating the defendant’s ability to function at trial on the basis of his or her functioning during the evaluation.

Only about one in five of those referred for a competency to stand trial evaluation are deemed incompetent, although this rate varies by jurisdiction. When a competency to stand trial evaluation is ordered by the court, the evaluating mental health professional must submit a report to the court detailing his or her findings. In a small number of cases, a competency hearing may be held to determine the issue of competency. Most of the time the judge’s decision is in accordance with the opinion of the evaluator. In fact, research indicates an agreement with the evaluator in more than 95% of cases—an extremely high concordance rate. There tends to be a good agreement between mental health professionals regarding ultimate opinions of competency to stand trial (80% or more); however, disagreement occurs more often regarding the defendant’s functioning on the specific psycholegal abilities that constitute competency to stand trial.

Incompetent Defendants

There has been a plenty of research on the topic of competency to stand trial, with convergence on the characteristics and psychological symptoms and conditions typically found among incompetent persons. A 2011 meta-analysis by Gianni Pirelli, William H. Gottdiener, and Patricia A. Zapf synthesized this research in order to capture the major differences between those found to be competent versus incompetent. Typically, incompetent defendants tend to be older, on average,

than those found to be competent. The slight majority of incompetent defendants are non-White, and more often, they are male, unemployed, and unmarried. Regarding psychological functioning, most incompetent defendants have a diagnosed psychotic disorder (e.g., schizophrenia, psychosis), and relatively few are diagnosed with personality disorders. Mental retardation, organic brain disorders, and mood disorders have also been associated with incompetence. In addition, those deemed incompetent are more likely to have had prior contact with the criminal justice system and a history of psychiatric hospitalization compared with their competent counterparts.

In 2007, Douglas Mossman identified psychosis and cognitive impairment as the two conditions under which a defendant is most likely to be found incompetent to stand trial. *Psychosis* refers to a broad category of disorders that are characterized by an inability to remain in touch with reality. Symptoms typically involve bizarre behavior, hallucinations, and delusions. If psychotic symptoms are severe enough to diminish one's ability to meet the standard for competency to stand trial, a defendant may be found incompetent. Similarly, *cognitive impairment* is a broad term for various cognitive deficits that may coincide with mental, developmental, or medical disorders. Intellectual dysfunction may also serve as a threshold condition for a finding of incompetence, but evaluators and legal decision-makers must be careful to establish that the cognitive deficits contribute to an inability to meet the specific standard for competency to stand trial.

It is important to note that a psychiatric diagnosis does not necessarily mean a defendant will be found incompetent to stand trial. In 2011, Pirelli and colleagues observed that, of those referred for a competency to stand trial evaluation and found to be competent to stand trial, 22.2% were diagnosed with a psychotic disorder and 27.9% were diagnosed with a personality disorder. The distinction between those adjudicated competent versus incompetent, therefore, is that the presence of a mental disease or defect significantly impairs an incompetent defendant's rational and factual understanding of the proceedings or his or her ability to participate in the defense. Conversely, those adjudicated competent may certainly have a mental disease or defect, but this does not impair

their ability to factually or rationally understand or participate in the proceedings.

Restoration to Competence

When a defendant is found to be incompetent to stand trial, he or she will likely undergo court-ordered treatment for restoration. Although this typically occurs in an inpatient setting, many jurisdictions have moved toward a *least restrictive alternative* policy, wherein outpatient treatment is to be used whenever possible. In addition, there has been a recent move toward providing competence restoration services in jail facilities.

Most incompetent defendants can be restored within 12 months (or fewer) and, once restored, will proceed with trial. Most jurisdictions require a periodic review of defendants undergoing treatment for restoration and have procedures in place to find a defendant *unrestorably incompetent* if restoration attempts have been unsuccessful after some period of time (defined by each jurisdiction). Defendants who are deemed *unrestorable* will typically have their charges dismissed.

The length of time for which an incompetent defendant can be detained varies by jurisdiction, with each state required to have statutes regarding restoration procedures and time lines as a result of the Supreme Court's decision in *Jackson v. Indiana* (1972). Prior to this, defendants who were detained for restoration were often confined indefinitely. In *Jackson v. Indiana*, the Supreme Court decided that incompetent defendants could not be detained for "more than a reasonable period of time necessary to determine whether there is a substantial probability" that they will regain competency in the foreseeable future (p. 738). Although seemingly unspecific, many states have adopted the exact language of *Jackson*, and others have included a more specific time frame in their statutes.

As far as treatment, restoration typically involves the administration of psychotropic medication to control symptoms of mental illness and education about court proceedings. But what about when a defendant refuses to take psychotropic medication? A series of Supreme Court cases have indicated that incompetent defendants may be forcibly medicated if it is justifiable and medically appropriate (*Riggins v. Nevada*, 1992) and necessary for the safety of the

defendant or others (*Washington v. Harper*, 1990), or it is likely to restore competency with minimal side effects and less intrusive methods are not possible (*Sell v. United States*, 2003).

Although the vast majority of defendants who undergo treatment for restoration are restored to competence within 6–12 months, there are two groups of defendants that are particularly difficult to restore. Defendants with chronic severe mental disorders with a history of multiple inpatient admissions, such as those with schizophrenia, are difficult to restore to competence, as are those with severe intellectual disabilities (formerly called *mental retardation*).

Specific treatment programs have been developed for defendants with intellectual disabilities (e.g., the Slater Method), and the available research indicates that although these programs show success in comparison with treatment as usual for this population, they are resource-intensive, and restoration often takes upward of 2 years.

COMPREHENSIVE CORRECTIONAL PLANS

Comprehensive correctional plans are evidence-based strategies that include a diversity of perspectives in order to collaboratively integrate mental health programming into the overall correctional programming. It accentuates the maxim that *working together works*. The United States has one of the highest incarceration rates in the world, with 5% of the world's population, but nearly 25% of the world's prisoners. Concomitant with the increase in the incarceration population, there has been exponential growth in the number of mentally ill individuals in U.S. jails and prisons. Today, at least 15–20% of U.S. prison inmates have a serious mental illness, and when including broad-based mental illnesses, the percentages increase significantly. This entry focuses on the role that correctional psychologists play in developing and implementing comprehensive correctional plans in order to collaboratively address emerging issues in managing prisoners with mental illness.

Developing Comprehensive Correctional Plans

The importance of mental health delivery systems has emerged as one of the top concerns of correctional officials in the United States. As a result, correctional psychologists, who comprise the majority of mental health director positions in state prison systems and have historically occupied the position of director of mental health for the Federal Bureau of Prisons, have become the leaders in developing and implementing effective comprehensive correctional plans.

In developing a dynamic comprehensive correctional plan, correctional psychologists must ensure the integrity and clinical-legal defensibility of the mental health services delivery system. In *Estelle v. Gamble* (1976), the U.S. Supreme Court determined that the Eighth Amendment to the U.S. Constitution requires that prison officials provide a system of ready access to adequate medical care, including mental health care. Thus, the federal government as well as state governments have a mandate to provide access to adequate mental health treatment in correctional institution settings. Accordingly, policies and procedures must be written to reflect compliance with community standards of care, national accreditation organizations, state and federal statutes, and relevant legal precedents.

Psychologists and psychiatrists serving as correctional mental health experts have identified five general rubrics necessary to establish a constitutionally adequate correctional mental health system. First is the identification of the essential elements of a comprehensive correctional plan, which are adequate physical resources regarding treatment program space and supplies; sufficient human resources; and adequate access for inmates to the physical and human resources within a reasonable period of time.

Second is the implementation of the necessary components of a defensible correctional mental health services delivery system, including but not limited to initial reception intake screening and assessment; a crisis intervention program; appropriate levels of care; a suicide and self-injury prevention program; a responsive staff referral and inmate request system; discharge/transfer planning, and prerelease planning for continuity of care in the community.

Third, a critical issue for a clinically defensible mental health system is the development of a mental health classification system. Such a classification system defines what mental health treatment and services are needed for whom, and when, where, and how they will be delivered.

Fourth is uniformity in defining serious mental illness. At present, there is a perplexing lack of agreement on the definitions of serious mental illness. As varying definitions of serious mental illness have emerged in consent decrees and settlement agreements, it is imperative to establish a uniform definition that has clinical-legal defensibility. For example, Dean Aufderheide recently proposed a standardized definition for serious mental illness germane to restrictive housing that was ratified by a national accreditation organization. The proposed definition for serious mental illness is as follows:

psychotic disorders, bipolar disorders, and major depressive disorder; any other diagnosed mental disorder (excluding substance use disorders) currently associated with serious impairment in psychological, cognitive, or behavioral functioning that substantially interferes with the person's ability to meet the ordinary demands of living and requires an individualized treatment plan by a qualified mental health professional(s).

Such a standardized definition of serious mental illness, along with a defined mental health classification system, provides a starting point to ensure that inmates have timely access to necessary care in accordance with their identified and assessed mental health needs.

Fifth is access to structured mental health services and treatment, which means an individualized mental health treatment and services plan developed with the inmate by a multidisciplinary treatment team, when feasible. Treatment plans need to be behaviorally written, reviewed, and revised as needed and have clear and measurable outcomes.

In order for a correctional mental health services delivery system to be clinically and operationally effective, it must be contextualized within the framework of a comprehensive correctional plan. The plan should integrate the mission requirements of interdisciplinary staff and incorporate their

knowledge, skills, and abilities to create a synergy that ensures public safety and access to necessary mental health treatment and services.

Expanding the Role of Psychologists in Comprehensive Correctional Plans

As corrections officials are called upon to respond to ensure the delivery of constitutionally adequate health care, they are recognizing the importance of including the expertise of psychologists. Moreover, psychologists are understanding that they must cultivate their own roles with a collaborative leadership structure in order to have a measurable impact on improving the correctional system as a whole. The following examples of shared leadership—called *shared collaboratives*—illustrate the expanded opportunities psychologists can have within the structure of comprehensive correctional plans.

The Consultant Collaborative

Skills such as understanding how human factors affect organizational functioning, data analysis, and system design are among the assets that correctional psychologists bring to a comprehensive correctional plan. At the institutional level, consultation with wardens and security staff regarding problematic mentally ill inmates provides opportunities to constructively reconcile the inherent tension between custody and mental health-care program needs. Consultation and input into the disciplinary process and evaluations for paroling authorities offer opportunities to demonstrate the value of psychological testing in improving decision-making processes. At the administrative level, this collaborative creates opportunities for psychologists to work with correctional officials and policy makers to develop best practices and implement evidence-based strategies to achieve custody, care, and cost efficiencies.

The Training Collaborative

There is a growing demand in the corrections field for collaborative training opportunities. In addition to training on suicide and self-injury prevention, for example, specialized modules with

other interdisciplinary staff, including crisis intervention team training, managing mentally ill inmates in restrictive housing, multidisciplinary management teams in inpatient units, critical incident root cause analysis, trauma-informed care, gender dysphoria, and reentry planning are all training opportunities that correctional psychologists can provide. This training collaborative is an ideal mechanism for psychologists to use their expertise to equip other staff with crucial knowledge about mental illness in order to improve inmate management and supervision of mentally ill offenders, while ensuring continuity of care and preparing inmates for reentry into their communities. Whether in a jail, prison, or with other constituents of the criminal justice system, shared training reinforces the values and goals to be shared by all staff at all levels in a comprehensive correctional plan.

The Assessment Collaborative

Perhaps the most auspicious opportunity to achieve cost, care, and offender management efficiencies is the assessment collaborative. Correctional officials seek reliable and valid data to improve accuracy in offender management decisions and post-release outcomes, while multidisciplinary treatment team members need objective data to clinically justify diagnostic and treatment dispositions. Significantly underutilized in correctional settings, the assessment collaborative brings objective data into offender management and treatment decision-making in comprehensive correctional plans.

The Behavioral Health Collaborative

This collaborative brings mental health and substance abuse services under a behavioral health paradigm. Co-occurring mental health and substance abuse disorders, often referred to as *dual diagnosis disorders*, are not uncommon in correctional settings. In prisons, approximately 30% of individuals with substance use disorders also have a major mental health disorder. Conversely, in jails, an estimated 72% of individuals with serious mental illnesses have a substance use disorder. In prisons, co-occurring disorder estimates range up to 11% of the total incarcerated population. Whereas many systems have separated mental

health and substance abuse programs, research indicates that for those individuals with co-occurring disorders, integrated treatment by a single provider is associated with better treatment outcomes. Although psychologists can be credentialed to provide the substance abuse component of the dual diagnosis, substance abuse staff cannot provide the mental health component. Therefore, the behavioral health collaborative provides correctional psychologists with an opportunity to collaborate with correctional officials in order to achieve significant program cost and care efficiencies in comprehensive correctional plans.

The Reentry Collaborative

Policy makers have begun to focus on reducing recidivism through effective reentry programming, and correctional officials have added reentry planning to their mission statements. Because inmates with mental illness, especially those with dual diagnosis disorders, recidivate at higher rates than inmates without mental illness, they have been the focus of attention in the corrections field. This collaborative allows correctional psychologists to expand their expertise and partnerships into the community, where continuity of care and necessary support and assistance services can be coordinated within comprehensive correctional plans.

In summary, correctional psychologists are expanding their role in comprehensive correctional plans using their unique expertise and skill set to develop metrics that identify maladaptive inmate behaviors, which can result in threats to institutional security, inmate and staff safety, and are costly in terms of human and financial resources. Although problems and obstacles may emerge when developing durable collaborations within a comprehensive correctional plan, by working together to strengthen partnerships and appreciating the needs and capabilities of all correctional staff, correctional psychologists can become leaders in developing dynamic and productive comprehensive correctional plans.

Conclusion

Whether in the role of an institutional clinician or agency mental health director, correctional

psychologists understand the importance of integrating mental health programming into the overall correctional programming to create new synergies. By implementing comprehensive correctional plans, correctional psychologists can have greater success in fulfilling their responsibilities as correctional professionals and to society.

CONFESSIONS

In law, a confession is a statement in an admission of guilt accompanied by a narrative account of the crime. Typically induced during police interrogations, confession evidence is common within the criminal justice system, is persuasive, and is highly incriminating in court—even if it was wrongfully obtained or coerced and later recanted. However, confessions are not infallible. Over the years, many innocent people have been wrongfully convicted and imprisoned after confessing to crimes that they did not commit. In 2017, the Innocence Project estimated that approximately 25% of all DNA exonerations involved a false confession.

Social, clinical, cognitive, and developmental psychologists, as well as other social scientists, have used a range of research methodologies in the empirical study of confessions. This research includes the study of individual cases, archival records, observations of police interrogations, surveys and other self-report methods, and laboratory and field experiments. Collectively, these studies have shed light on three sets of issues: the processes of police interrogation; personal and situational risk factors that can lead suspects to confess, even if they are innocent; and the consequences that follow from confessions, in terms of how the crimes are investigated and then adjudicated in court.

Inspired by the numerous wrongful convictions that have surfaced, psychologists are particularly

interested in false confessions. Indeed, it is useful to distinguish between three types of false confessions: (1) *voluntary*, which arises when an innocent person volunteers a confession to police in the absence of any pressure (e.g., to protect someone else or to gain attention in a high-profile crime); (2) *coerced-compliant*, whereby an innocent person agrees to confess as an act of compliance in order to escape a stressful interrogation, avoid a threatened harm or punishment, or gain leniency or other perceived rewards; and (3) *coerced-internalized*, when an innocent person, during an interrogation in which police present false evidence of guilt, not only agrees to confess but also comes to believe that he or she committed the crime, a belief sometimes accompanied by false memories. This entry focuses on false confessions, discussing the processes of police interrogation, the risk and consequences of false confessions, and policy and practices.

Processes of Police Interrogation

As embodied by the Reid technique—a U.S.-based psychological approach to interrogation that relies on confrontation, trickery, and deception—suspects are questioned in a two-step process. The first step consists of a *preinterrogation interview* designed to ascertain whether the suspect is telling the truth, and hence innocent, or whether the suspect is lying, and hence guilty. In this process, the detective asks a list of *behavior-provoking* questions that ostensibly evoke verbal and nonverbal behaviors in the suspect that are believed to betray deception (e.g., broken or avoided eye contact, overly rigid posture, slouching, fidgeting, and touching the face).

Although these verbal and nonverbal behaviors may seem to signal deception as a matter of common sense, research has consistently shown that these cues do not produce accurate deception detection. Overall, controlled studies show that people are not adept at distinguishing between truths and lies and are only about 54% accurate. Moreover, while training in the use of these verbal and nonverbal cues increases confidence, it does not increase accuracy. In the context of a preinterrogation interview, the result is that honest and innocent individuals are often misidentified for the second step of the process: *interrogation*.

Interrogation is an accusatory, guilt-presumptive process of questioning aimed at eliciting confessions from suspects whose denials were judged deceptive. During the first half of the 20th century, the U.S. Supreme Court outlawed physically coercive *third-degree* tactics that are likely to produce involuntary and possibly false confessions. As a result, police learned to use subtler, more psychologically oriented tactics. Although different approaches have evolved, all have three features in common. First, the suspect is physically isolated, questioned in a small, bare, windowless room. Second, police confront the suspect with accusations of guilt and presentations of incriminating evidence in an effort to communicate that denial is futile. As part of this confrontation, detectives in the United States are permitted by law to present false evidence (e.g., DNA, a fingerprint, hair sample, eyewitness identification, failed polygraph)—even if no such evidence exists. Third, police express sympathy and understanding and minimize the crime by offering the suspect moral justification and face-saving excuses. They may suggest, for example, that the crime was accidental, provoked, pressured by others, or otherwise attributable to external factors. By implying leniency in punishment, minimization makes it easier for a suspect to confess.

The Risk of False Confessions

When it comes to false confessions, it is clear that some individuals are more vulnerable to influence than others. Developmental psychology research shows that children and adolescents are particularly prone to make decisions that gratify immediate goals, often to the neglect of the harmful longer term consequences (e.g., agreeing to confess to a crime that they did not commit in order to escape a stressful interrogation) especially while under stress. Hence, it is not surprising that juveniles are disproportionately represented in the population of known false confessors. Also overrepresented are adults with intellectual impairments and/or certain types of mental illness who may not comprehend their rights, or grasp the consequences of confession, or who may be prone to social influences on compliance and internalization.

Although some individuals are at greater risk than others, no one is immune to the pressures of police interrogation—especially when tactics are

excessively used. For example, one situational factor that can put innocent suspects at risk is a lengthy period of custody and interrogation. Observational studies show that most interrogations last between 30 min and 2 hr. Yet analyses of proven false confessions show that the interrogations in which they were elicited typically lasted for many hours.

A second interrogation factor that can lead innocent people to confess is the presentation of false evidence. As noted earlier, police in the United States are permitted to mislead suspects about the presence of incriminating evidence, even if there is no such evidence. The aim is to increase the anxiety associated with denial and create a state of despair. This tactic is found in numerous police-induced false confession cases. With strong roots in basic psychology, laboratory experiments using a variety of methods confirm what has been observed in actual cases: The presentation of false evidence significantly increases both the number of innocent people who agree to sign a confession and the number who come to internalize a belief in their own guilt. It is now clear that while this lawful technique can get guilty perpetrators to confess, it can also have devastating effects on those who are innocent.

A third interrogation factor seen in numerous proven false confession cases is minimization, the technique by which police minimize the seriousness of the crime. Minimization is designed to reduce the anxiety associated with confession by suggesting to the suspect that his actions were morally justifiable, the result of an accident, or someone else's fault. Controlled experiments show that minimizing remarks lead people to infer a promise of leniency in sentencing, even when no such promise is explicitly made. These findings help to explain why many innocent people, once exonerated, claim they had confessed expecting to go home—or back to school, as in the case of 16-year-old Brendan Dassey, whose police-induced confession was seen in the 2015 documentary film *Making a Murderer*. Dassey was interrogated about a murder that the police suspected his uncle of committing. After hours of interrogation involving minimization, Dassey confessed to participating in the crime. Despite a lack of evidence against him, Dassey is living out a life sentence on the basis of his confession.

Consequences of Confession

Legal scholars have long known that confession is a powerful form of evidence in the criminal justice system. If a recanted confession is deemed voluntary by a judge at a pretrial suppression hearing, it is admitted as evidence against the defendant. Mock jury studies show that confessions almost invariably produce convictions at trial even when jurors determine that the confession was coerced, even when there is no other substantial evidence, even when the confession was reported by a secondhand informant who was motivated to lie, and even, at times, when the confession is contradicted by exculpatory DNA tests.

The power of confessions is rooted in the commonsense notion that people would not admit to crimes they did not commit. This belief leads judges, juries, the media, and the public to inherently trust confession evidence. Often, this commonsense belief is well placed. It does not, however, provide an antidote in court to the problem of false confessions. Analyses of actual cases provide further explanation for why people uncritically accept false confessions. Specifically, research shows that a vast majority of proven false confessions contain not only an admission of guilt but accurate nonpublic details about the crime (e.g., the position of the victim's body, what he or she was wearing, what the crime scene looked like). In cases in which the confessor was later proved innocent, these details—which helped to prove that the confessor had guilty knowledge—reveal a process of *contamination* by which police had wittingly or unwittingly introduced these details to the suspect through the processes of interviewing and interrogation.

It is important to note that confessions can not only influence judges and juries at trial, but they can also alter the course of an ongoing investigation before it ever reaches the courtroom. Drawing on basic psychological research on confirmation biases, studies have shown that once detectives, forensic or medical examiners, polygraph examiners, eyewitnesses, alibis, and others involved in an investigation form a strong hypothesis about the identity of the perpetrator, that hypothesis corrupts their perception of the evidence. In several studies, information that a suspect had confessed led witnesses to misidentify that confessor in a

lineup or perceive his handwriting as a match to a note found at the crime scene. In one study, professional polygraph examiners who were told that the suspect had confessed were more likely as a result to report that the suspect's polygraph chart indicated deception. Even latent fingerprint experts are influenced by strong contextual cues such as confession.

Matters of Policy and Practice

It is safe to assume that most confessions taken by police and those subsequently form the basis of guilty pleas and convictions at trial involve the actual perpetrators of crime. It is also clear, however, that some innocent people are misidentified for interrogation and also induced to confess. In these cases, society stands to lose twice: first, when innocents are wrongfully convicted for crimes that they did not commit; second, when the real perpetrators of those crimes remain free to victimize others.

The U.S. criminal justice system provides a singular mechanism by which individuals accused of a crime can protect themselves from self-incrimination. In the landmark case of *Miranda v. Arizona* (1966), the U.S. Supreme Court ruled that statements made by a defendant during an interrogation are admissible in court only if the defendant had been apprised of his or her constitutional rights to silence and to counsel—and then voluntarily, knowingly, and intelligently waived those rights. Although *Miranda* was aimed at changing the dynamic of police interrogations, which the Court described as *inherently coercive*, its effectiveness is a matter of dispute. As previously noted, empirical studies have shown that certain segments of the population—most notably, young adolescents and adults who are intellectually impaired—do not fully comprehend their rights and how to implement them. Moreover, statistics show that most people tend to waive their rights—in part because police have become highly skilled at convincing suspects to do so and in part because people believe that invoking their rights will lead authorities to infer their guilt. To further complicate matters, research shows that innocence itself is a state of mind that leads innocent people to waive their rights because they have nothing to fear or hide. In short, there is reason

to believe that Miranda warnings do not adequately protect the citizens who need it most—those accused of crimes they did not commit. Other safeguards, therefore, are needed.

Over the years, some researchers have advocated for measures to protect vulnerable suspect populations and limit the use of psychologically coercive interrogation practices. The most important proposal for reform, however, is to require the video recording of all suspect interviews and interrogations—the entire process, not just the final confession. This was the primary recommendation in a White Paper of the American Psychology-Law Society. Video recording both serves as a deterrent to excessive police tactics and preserves an objective and accurate record of what transpired during interrogation sessions that are often later in dispute. Aided by these video recordings, judges and experts can better determine the voluntariness and reliability of the resulting confession. Many states and jurisdictions have adopted this practice—with positive results.

CONTINGENCY MANAGEMENT

Contingency management (CM) is a systematic reinforcement system founded on basic principles of behavior analysis and operant psychology used to increase drug abstinence and treatment compliance of patients. CM provides vouchers, money, or other reinforcers contingent on drug abstinence, program attendance, social or job skills training, and completing treatment goals of the specific CM program. By increasing the reinforcement for abstinence and nondrug use behaviors, CM seeks to manage the contingencies that influence drug use. The idea behind this is the notion that the effect of reinforcement on a behavior is relative to the reinforcement available for other behaviors. So, drug use occurs because it is reinforcing, but when the relative rate or amount of reinforcement for abstinence and completing treatment goals is increased, abstinence and completing treatment goals increase. With CM, as the value of abstinence and nondrug behaviors increases with vouchers, money, or other reinforcers, the relative reinforcing value of drug use decreases, thus drug use decreases. CM, then, effectively increases abstinence of abused substances across a wide range of patient populations.

General Procedures and Principles

While particulars of any CM program vary, simple behavior analysis principles form the basis of all CM programs.

Behavioral Contracting

A behavioral contract between the patient and clinic (or professional in charge of the CM program) is a central element to virtually every CM program. A behavioral contract explicitly and clearly states the behaviors monitored, frequency and times of monitoring (e.g., drug testing), and contingencies of reinforcement—what, when, where, and how frequently reinforcement will occur and exactly what behaviors must occur for reinforcement to occur during these times.

Behavior and Measurement

The behaviors to be reinforced must be precisely defined and objectively measured. Drug

abstinence is usually defined as providing a negative drug test. Self-report is unreliable. Many patients are polydrug abusers. A CM program must specify if abstinence from all abused drugs, such as opiates and cocaine, is necessary for reinforcement or if, at least initially, abstinence from a single substance is sufficient to meet the criteria for reinforcement. The frequency of the behavior and that of the measurement must also be considered. If a substance was abused only a few times a year, such as an occasional cocaine binge, most tests would be negative, and the patient would receive reinforcement for abstinence even though the patient's rate of drug abuse did not decrease. The initial rate of drug use must be frequent enough to reliably detect periods of abstinence. Measurement must also be frequent enough to reliably detect both drug use and abstinence. With infrequent measurement, a test could show positive even though most of the time the patient was abstinent. Conversely, a test could be negative even though the vast majority of time, except for a few days preceding testing, the patient was using. Therefore, CM programs test frequently (daily to once a week). Compliance with treatment plans and meeting treatment goals are also precisely defined, objectively measured, and reinforced. These behaviors may include attendance at and participation in individual or group therapy, medication compliance (especially for antagonists such as naltrexone and disulfiram), building vocational skills, filling out job applications, completing assignments toward earning a GED, General Educational Development or even engaging in socially appropriate behaviors in the clinic.

Reinforcement Considerations

Variables regarding reinforcement must be established. The more frequent, immediate, and valuable the reinforcers are, the more effective the program will be. A benefit of vouchers, or any conditioned reinforcers (e.g., tokens), is that they can be delivered frequently and can be immediately contingent upon target behaviors when goals are met. Especially, initially, when the program is building trust and patients must *buy into* the program, vouchers are exchanged for previously determined backup reinforcers frequently. This way patients learn contingencies and learn that

their behavior matters. "If I don't use, if I test clean, I get a voucher. If I attend sessions I get a voucher. If I do my work I get a voucher. When I get vouchers I can trade them for bus tokens, McDonald's coupons, movie passes, or a take-home weekend dose of methadone." Effective CM reinforcement procedures can have the added benefit of ameliorating learned helplessness and help facilitate behavioral activation.

Reinforcer Value

Because the value of a reinforcement must be greater than the value of drug use to see increased abstinence, at times, it is beneficial to adjust the level of the reinforcement to see an increase in abstinence for a particular use. To increase the value of vouchers in some CM programs, vouchers are used to buy chances or draws for a large prize (e.g., US\$250 or a television). All draws result in reinforcers but most are small (US\$1 or a food coupon). Such contingencies make reinforcement variable. Variable reinforcement increases persistence in the reinforced behaviors (e.g., abstinence, attendance). Drawings are also exciting and socially reinforcing events for patients, further increasing their effectiveness. Making the receipt of large reinforcers infrequent also has the advantage of keeping the cost of CM down.

In many CM programs, as patients are abstinent for longer periods of time, the amount of reinforcement for each negative test results in a greater amount of reinforcement (e.g., escalating bonuses, more chances per drawing, more money). But a positive drug test resets the reinforcer amount to its initial, lower level. Increasing reinforcement for remaining abstinent increases the probability patients will remain abstinent.

Escalating bonuses may also be conceptualized as reinforcing successive approximations toward the terminal goal of sustained abstinence. Reinforcement of successive approximations is a basic, highly effective, behavior procedure that is facilitated with priming or reinforcer sampling. With priming, a patient is given a voucher and its backup reinforcer, or other reinforcer, immediately upon first entering the clinic for the initial visit. This reinforcer sampling teaches patients that the vouchers do in fact have value and that patients are not being lied to or misled. Entering the clinic is a necessary

first approximation toward participating in the CM program and becoming abstinent.

Effectiveness of CM

Overall Outcomes

Compared to other treatments (e.g., methadone maintenance therapy for heroin addiction), CM consistently results in statistically significant and clinically significant outcomes for increased abstinence and decreased relapse across the spectrum of drug abuse problems with substances such as heroin and other opioids, cocaine, crack cocaine, methamphetamine, alcohol, marijuana, and tobacco addiction or dependency. Multiple meta-analyses and literature reviews consistently find CM to have efficacious outcomes that include increased lengths of time remaining in treatment, increased drug-free urine samples, and improved treatment and medication compliance. Although not perfect, the desired outcome measures, whatever they may be for a particular study, are generally 2 or 3 times greater for CM compared to the alternative, usual, treatments of any particular study.

Adjunct Benefits

Beyond abstinence, patients and clients in CM programs consistently report a wide range of beneficial effects of CM, including experiencing enthusiasm about the program, social integration into the clinic, and increased feelings of self-esteem. Patients report a shift in subjective feelings of being forced to participate to avoid aversive consequences, such as being reported for drug use parole violations, to willing participation, freely chosen in pursuit of the positive reinforcers available in the CM program.

Staff, counselors, and clinicians report that patients in CM programs are more likely to confide in counselors than in other types of abstinence programs. Both staff and patients feel less coercion to participate in treatment. Once patients are actively working toward treatment goals, staff feels increasingly empowered. Rather than perceiving themselves as mere methadone dispensers and drug testers, counselors can actually counsel. Staff can explore with the patient in responsible, social, and interpersonally healthy ways to gain and maintain abstinence and meet

other treatment goals. Interpersonal relations often improve as a result of being in a CM program. When vouchers are exchanged for fast food or food coupons, bus tokens, or other shareable reinforcers, patients often share these with family members or significant others, thus strengthening social relations outside the clinic. The receipt of vouchers, or the exchange of vouchers for backup reinforcers, is often a great source of social reinforcement and acknowledgment. This social reinforcement improves interpersonal relations among patients, between patients and staff, and further strengthens the CM program, likely improving outcomes. Ideally, once treatment goals are met, patients have better social and vocational skills and the natural reinforcers for these behaviors, a paying job, a richer and more satisfying family and social life, will maintain these behaviors with abstinence continuing once CM is completed.

Populations and Program Locations

The treatment populations of CM programs have ranged across the spectrum of drug abuse populations with most being methadone or opioid detoxification patients, cocaine abusers, or polydrug abusers. Cigarette and marijuana smokers and alcohol abusers (Veterans Affairs patients and chronic public offenders) have also participated in CM programs. Most programs have been in university research clinics, but CM programs and techniques are increasingly appearing in community-based treatment centers such as the New York City Health and Hospital Corporation Addiction Treatment Service.

There is strong support for CM to be applied in more settings and environments such as correctional settings and elsewhere in the criminal justice system. Preadjudication drug court, for example, would be an ideal setting for CM. Studies in the 1960s through the 1990s showed that CM programs in correctional institutions were successful at reducing aggression and violence and increasing rule-following, work, prosocial, and educational outcomes. Despite these benefits, the political climate that fostered the *war on crime* approach prevented the pursuit of effective applications of CM in correctional settings.

Barriers, Limitations, Objections, and Extensions

The initial cost of implementing CM is its biggest barrier. Frequent drug tests and different types of reinforcers can quickly become expensive. These costs are offset somewhat through the success of the program. However, even the most costly CM program is much less expensive than the usual cycle of use–arrest–relapse–repeat. Staff often have misconceptions about and resistance to CM, viewing it as cold, controlling, uncaring, or mechanistic. These misconceptions typically come from popular but dated, restricted, and often false media portrayals of behavioral psychology, ranging from the 1971 movie *A Clockwork Orange* to the popular television show *The Big Bang Theory*, which began airing in 2007. Oversimplified caricatures of behavioral psychology are also often taught in academia, called *rat psychology* or *animal training*, but like modern medicine and biology, basic principles and processes are first established in simpler systems, with animal research, then applied to increasing complex systems and eventually to humans, as the principles involved are better understood. While CM does demand explicit behaviors for contingent reinforcement, it is an effective treatment method, not cold or uncaring, and with direct experience staff normally become receptive to it.

While CM is generally associated specifically with a drug treatment approach, any system that manages contingencies of reinforcement for behavior such as token economies is CM. Its core philosophical driver is consistent with social exchange theory, which views all human interaction as the exchange of rewards and punishments. Many of the contingencies and criteria for these exchanges are subtle and difficult to discriminate, especially for psychotic and drug-abusing populations. CM makes the contingencies and social expectations explicit, clarifying them and thus empowering those struggling.

Paying or otherwise reinforcing abstinence for drug abusers is patently objectionable for some. Yet many jobs and subsequent pay, including jobs in treatment, corrections, and medicine, require drug testing and abstinence as a condition of employment. Remaining drug free is a requirement for access to many reinforcers in society. Many social and interpersonal relations are dependent on abstinence, and in some cases, the contingency is made explicit: “Honey, you have to choose between me

or the bottle/pipe/needle.” CM simply makes explicit many of the contingencies that are already pervasive across the human experience. Because participants in CM often have an extensive life history of substance abuse, little academic, vocational, or social skill training comes from impoverished environments with high rates of violence and low employment opportunities; even the best programs, CM or otherwise, will not always result in success.

Nevertheless, to the extent that CM actually manages effective contingencies for abstinence with objective behavior measurement, behavioral contracting, and contingent reinforcement for abstinence, CM is one of the most effective treatment approaches available.

CO-OCCURRING DISORDERS IN INCARCERATED OFFENDERS, TREATMENT OF

The term *co-occurring disorders* (COD) in the field of corrections usually refers to a substance use disorder (SUD) concurrent with a mental health disorder (MHD). These disorders happen in close

proximity of time and usually get worse when left untreated. MHDs usually include disorders of mood, anxiety, and lack of touch with reality, such as schizophrenia. An SUD indicates that an individual is using a substance that significantly affects his or her cognitive, behavioral, and physiological functioning accompanied with recurrent substance-related problems. Having an SUD sets up an incarcerated offender for a greater likelihood of developing a mental health problem.

Treating both disorders together is extremely difficult due to the number of clinical issues that interact and can complicate treatment; Integrated Dual Diagnosis Treatment is an evidenced-based practice to address this complication. This population often finds itself homeless when not incarcerated and has higher rates of arrest than offenders without COD. Prisons and jails are not typically equipped to deal with this population, and there are not enough programs to meet their needs. Greater success has been recognized by treating this population in community settings, where there are more resources and stronger links to treatment.

In this entry, treatment is discussed in terms of those incarcerated in prisons, jails, or community settings. The scope and type of treatment may vary within and across levels of incarceration.

Need for Comprehensive Assessment

Before developing a treatment plan, it is key to have a comprehensive assessment performed by a mental health professional trained in treating both types of disorders. This assessment will reveal specific treatment components needed for an individualized treatment plan.

First, a clear and accurate picture of an individual's mental health problems such as depression, hallucinations, delusions, or other types of mental illness is needed. A history of suicidal thoughts and behavior, as well as any family history of mental illness, should also be determined.

Second, current substance use and substance abuse history are assessed. This history typically includes the types of illegal and prescription drugs used, the inception of the drug use, the dosages and times of frequent use, and whether the individual has ever abstained from use and/or received treatment for substance use.

Third, interaction between substance abuse and mental health problems for an individual as well

as the patterns of symptoms exhibited and the time sequences between substance use and mental health symptoms are determined by questioning the individual. Observing mental health symptoms after the individual abstains from substance use for a period of time can help to ascertain a true mental health diagnosis.

Fourth, criminal history dating back to childhood, including mental health symptoms and/or use of substances in relation to criminal activity, and amount of violence or aggression used in each offense are assessed. In addition, the assessment notes whether mental health symptoms and/or use of substances were ever associated with criminal history.

Finally, health-care needs, such as past diseases or current problems related to substance use and/or mental health, are assessed. Personal health-care needs are often neglected by those with COD.

Motivation for Change

There are three pre-action stages—precontemplation, contemplation, and preparation—that most individuals experience prior to being ready to make a change. Ambivalence for change related to substance use behaviors is noted at each stage despite negative consequences and pain in the individual's life. If the treatment professional pushes change too hard, the individual may rebel and shut down. Thus, the treatment professional should be nonjudgmental, nonconfrontational, and collaborative when addressing an individual's COD needs. The goal is to ask questions that prompt the individual to think about his or her substance use, to listen rather than to tell, and to provide educational exercises to guide the individual toward making meaningful changes for self. This approach respects the individual's cultural background and is concerned with how the individual with COD views his or her treatment needs. Corrections professionals can use a motivation-for-change instrument to assess readiness for treatment for SUD. Two such instruments are the University of Rhode Island Change Assessment and the Stages of Change Readiness and Treatment Eagerness Scale.

When an inmate is assisted in moving toward the stage where he or she is ready to work on goals and objectives toward recovery (action stage), a relapse prevention plan may be

developed. This plan is intended to identify daily triggers and life changes needed for a better quality of life by developing effective strategies that compete with the desire to use illegal drugs as coping tools. The inmate also learns healthy coping strategies to prevent mental health relapse. Empowerment of the inmate and responsibility are stressed, so the inmate sees how his or her choices affect outcomes and those around him or her. This plan is shared with positive social supports which can hold the inmate accountable and encourage him or her to follow the plan.

Integrated Dual Diagnosis Treatment and Risk-Needs Models for COD

Research has supported that the model that works best in treating COD is one of integrating treatment for both SUD and MHD by the same clinicians in the same setting. Historically, these disorders have been treated separately by separate systems. Unfortunately, these systems often are riddled with problems related to payment, treatment coordination, and measuring success in their treatment approaches across systems.

Corrections research follows a Risk-Needs model, which suggests that offenders with the greatest risk to recidivate, as measured by a risk-needs instrument, should receive the highest dosage of services to address their criminogenic needs. High-risk offenders who have COD make the greatest gains when their criminogenic factors are addressed. Those factors subject to change are called *criminogenic needs* and may include substance use, employment, criminal peers, and antisocial beliefs and attitudes. Research supports that these factors are the most highly associated with high rates of offending. By individualizing treatment to address criminogenic needs, rates of reoffending can be minimized. The Risk-Needs model, used in combination with the Integrated Dual Diagnosis Treatment model, gives the clinician the most effective approach in treating this challenging population.

Other Modalities of Treatment

In the corrections system, therapeutic communities are long-term (6–24 months), highly intensive treatment programs. Most who participate in these programs are recovering individuals exposed

to a variety of treatment modalities, including groups, community meetings, individual counseling, and structured activities, to learn to empower themselves. Although therapeutic communities have been around for quite some time for individuals who have an SUD, they have only recently been adapted to be individualized and flexible for those with COD. Moving through the program is more individualized and educational than the traditional therapeutic community. Treatment stays can be longer, and more privileges and rewards are offered at a higher frequency. Groups and daily activities can be of shorter duration to help keep the individuals engaged. Treatment should be on a highly structured schedule. All staff working with these individuals are cross-trained with realistic expectations for behavior change, less confrontation, and more education related to managing medication and mental health symptoms.

Another component of treatment is the social skills-building approach. For those with COD, research shows that developing self-control strategies, including problem-solving, anger management, and general coping strategies, is helpful. Skills-building is taught through modeling and role-playing; individuals are taught to break down a specific social skill into steps and role-play each sequential step until the skill is learned. Repetition is necessary. Just like learning a golf swing, specific parts of the stroke are broken down and rehearsed separately and together until a smooth swing is automatic. There are many social skills inmates can choose. Each skill can be individualized to a specific inmate's situation such as how to monitor unpleasant symptoms, how to manage medications, how to prevent relapse, and how to deal with leisure time.

Another component of treatment is the cognitive behavioral approach. The inmate learns to identify errors in thinking and is taught healthy thinking replacements. An inmate, for example, may learn to identify self-centered thinking: "I deserve money from him because he has more than me" and learns a positive self-statement: "I have no right to take what does not belong to me." The inmate can then practice positive self-talk in role-play. The inmate learns a system for identifying and changing unhealthy thoughts, and with practice, the inmate can change unhealthy thought patterns. Peer support groups and 12-step groups

can be effective if they are adapted and modified to accommodate the effects of the MHD. Two such groups are Dual Recovery Anonymous and Double Trouble in Recovery.

A final area of treatment is providing effective case management services that help link inmates with COD treatment services while incarcerated as well as when they leave the institution. Effective case management helps individuals maintain stable mental health and rely on prosocial activities rather than on substance use. There is typically an active case manager in the correctional institution who helps individuals with COD manage their treatment within the facility. There are also case managers in the community upon reentry. Effective case management can lower the chances of an individual with COD from experiencing a decline in overall functioning, which results in fewer hospital visits and a better continuity of services.

Final Thoughts

Several key factors help create successful experiences for inmates with COD. Treatment needs to be individualized and flexible, as this is a fragile population who may not be able to comply with task demands and inflexible procedures. Line staff within correctional facilities who work the majority of the time with inmates with COD need extensive education on an ongoing basis in both mental health and substance abuse issues. They need to be encouraged to share information with treatment staff who are facilitating groups and providing individual counseling sessions. It is imperative to provide close supervision for inmates with COD, as they constantly need help and redirection. They also need opportunities to express their feelings, especially early in the program. Initial fears must be addressed, and the inmates must be reassured that their basic needs will be met throughout their stay. It is also important for inmates with COD to have a positive peer culture that encourages learning from one another and becoming empowered rather than always relying on staff for an answer. Staff need to provide the structure, accountability, and safety to allow inmates to learn crucial skills and to ensure that peer support is encouraged.

In addition, family involvement needs to be encouraged. Families and significant others will be

an extremely important part of recovery when the inmate leaves the institution. Families also need to be educated on how best to interact with their loved ones to minimize the risk of relapse. It is key to use a motivational assessment to always try and match the COD treatment plan with the corresponding stage of change for the individual related to substance use. Staff need to meet in weekly staff meetings with individuals to discuss their COD needs, identify successes in the treatment plan, identify obstacles to the plan, and make any necessary changes. Plans often need to be updated multiple times during an individual's course of treatment. Meeting regularly with individuals not only helps the individuals feel more empowered but also they start to recognize small steps of improvement. These small steps of improvement add up to great steps of accomplishment and are a springboard for successful community reentry.

Due to the need for highly trained staff and the creation of highly specialized programs, there is a dearth of treatment in prison and jail settings for those experiencing COD. The system will need to be creative in coming up with sources of funding to adequately train staff to identify and systematically treat this most needy population.

CORPORATE CRIME

Corporate crime refers to crimes committed by a corporation or individual acting on behalf of a corporation. Usually, such crimes are financial in nature and benefit the company or individuals within the company. Such crimes might consist of insider trading (e.g., providing nonpublic and privileged information to a third party for

investment purposes) or antitrust violations (e.g., predatory pricing to drive competitors out of business). Corporate crimes may also consist of avoiding losses or negligence. Some examples include misrepresentation of accounts in order to artificially drive up stock prices or hide losses or hiding environmental offenses in production in an attempt to maintain high levels of productivity or avoid financial penalties. Scholars such as James William Coleman and Edwin H. Sutherland considered corporate crime to be a specific subset of the larger umbrella of white-collar crime. In other words, all corporate crimes are white-collar crimes, but not all white-collar crimes are corporate crimes.

Corporate crimes are committed in corporate settings and sometimes (but not always) require some business acumen or financial knowledge. For example, a plumber intentionally overcharging for replacing a sink pipe would not be considered a corporate crime, although it would still be considered financial dishonesty or fraud. Moreover, individuals who commit corporate crimes often do not fit the demographic and criminological profile of other types of offenders. Whereas younger individuals from disadvantaged backgrounds (e.g., financially impoverished or low education) are more likely to engage in noncorporate offenses, corporate crime offenders are generally older and from more socioeconomically privileged and educated backgrounds. Finally, corporate crime offenses are difficult to prosecute. For example, such difficulty stems from the thin boundaries that obfuscate the difference between aggressive (but legal) business practices and illegal ones. Such difficulty in prosecution also stems from the nature of the offenders. Corporate leaders and corporate entities are seen as vital to the everyday fiscal health of a country, and there may be hesitation to aggressively prosecute such individuals for fear of the subsequent impact on a nation's economy. Thus, such individuals are less likely to be prosecuted with the same severity as other types of financially based crimes that do not fit a corporate crime profile (e.g., burglary, financial scams).

Related to corporate crime, but within the scope of legal activity, are financial behaviors that are legal but remain unethical. One example of this type of behavior might be a financial broker encouraging a client to move money around or take on unnecessary risks to increase broker fees. Such behaviors, although legal, still have a

negative impact on society. Further, it may be the case that these unethical activities do cross over into illegal territory. Whether illegal or merely unethical, the dispositional and situational forces that drive one's willingness to engage in such behaviors are likely to be similar.

Situational Perspectives on Corporate Crime

From a situational perspective, there are three primary components that help predict the likelihood that someone will commit a financial offense: rationalization, nonshared financial pressures or financial need, and opportunity. These three components have often been referred to as the *fraud triangle*, a term originally coined by Donald Cressey in 1950. These components were identified by Cressey after interviewing numerous corporate offenders and listening to their explanations for the crimes and the factors that prompted their engaging in the crimes.

Rationalization is not only a major factor behind committing corporate crimes, it has a long history in psychology of being linked with antisocial behaviors. Rationalization is particularly prevalent in corporate crime because the aforementioned boundaries between legal and illegal are generally thin. For example, holding a gun to a cashier for the contents of a register is fairly easy to diagnose as a crime. However, whether one has fully disclosed the risk involved in a particular transaction to a client or has shared information about a stock price that has not been readily made public is sometimes a difficult distinction to make. Thus, one's ability to rationalize a given behavior plays a key role in corporate offending; the more equivocal it is as to whether a crime is being committed, the easier it is to rationalize the offense. Some additional factors that make rationalization easier include, but are not limited to, psychological or physical distance from a victim, a sense that the crime is commonplace, a sense of entitlement, and a sense of injustice. For example, an individual committing an antitrust violation may feel that his or her behavior is simply what one has to do in the modern business world to survive and get ahead, and those who are being harmed are simply faceless consumers. Another example might be individuals who misrepresent stock prices in a large corporation with the rationalization that

they are put in an unfair position and only the wealthy stockholders in another place would pay the price.

Nonshared financial pressure refers to financial need that is generally not within socially acceptable boundaries (e.g., a car loan). For example, an individual with a drug addiction, gambling problem, or a socially unacceptable private expense would meet this criterion. Thus, there are few (if any) legitimate avenues to pursue to alleviate the expense, at least not sustainably. Although debatable, perceived financial need may be just as powerful as actual need. Further, extreme financial need, even if socially acceptable, may drive temptations toward corporate crime. For example, financial pressure would also be felt when a company is in danger of bankruptcy. Individuals may feel they had *no other choice* when committing the crime because they did not want to see their businesses fail. Further, there may even be altruistic reasons for corporate crime, such as when individuals engage in misreporting assets to avoid losing some of their workforce. Such perceived need may push individuals toward corporate crimes.

Finally, there is opportunity. The sense of ease surrounding the ability to commit corporate crime combined with a more hidden opportunity provides greater likelihood that an individual will commit fraud. Some opportunities may be as simple as creating a fake account to hide expenses or as socially complex as a competitor hinting at a price fixing discussion. While all three fraud triangle components must be present for fraud to take place, the *more* salient one factor is, the *less* powerful the other two need to be. The fraud triangle is a versatile model that can be applied to virtually any corporate crime or fraudulent financial behavior.

Dispositional Perspectives on Corporate Crime

Research on dispositional traits linked to financial crime has spanned several key areas. The Hogan Development Survey used diagnosable personality disorders as a guide to create an inventory that provided indices of problematic traits in corporate settings. The Hogan Development Survey includes traits such as excitable (borderline), skeptical (paranoid), cautious (avoidant), reserved (schizoid), leisurely (passive-aggressive), bold (narcissism),

mischievous (antisocial), colorful (histrionic), imaginative (schizotypal), diligent (obsessive-compulsive), and dutiful (dependent). The Hogan assessments are able to identify some personality constructs that are problematic in work settings, although not all of them would be linked with corporate crime. For example, reserved and diligent would typically be unassociated with corporate crime, whereas bold and mischievous would be good predictors.

Another personality taxonomy that has gained serious interest in the realm of financial misbehavior is the dark triad of personality. The *dark triad*, a term coined by Delroy Paulhus and Kevin Williams in 2002, refers to the three most studied personality traits that are linked with interpersonal harm. These traits consist of impulsive and reckless psychopathy, strategic and cynical Machiavellianism, and grandiose and entitled narcissism. At their core, all of the dark triad traits lack honesty and empathy.

Only recently have scholars looked more closely at the relationship between psychopathy and illegal behavior within a corporate setting. Robert Hare noted that psychopathic individuals may not only be found in abundance in prison, but on Wall Street as well. Fast-paced, high-risk, and high-payoff environments are likely to appeal to individuals with psychopathic tendencies because they fit their fast-paced, reckless, and aggressive character. Psychopathic individuals are versatile in their criminal activities and lack remorse. Further, they are drawn to immediate gratification, such as money or power, which makes them unlikely to weigh the consequences of their actions. Thus, psychopathy is most likely linked with all forms of corporate crime. There has been recent interest in what has been called *corporate psychopathy*. Further, psychopathy has been linked with abusive supervision and poor outcomes in corporate settings. Although some have argued that psychopathy can be beneficial in the corporate world, it is important to note that only psychopathic manipulation and callousness have been linked to positive evaluations in employees. However, the impulsive and antisocial aspects of the psychopathy trait are linked with poor performance.

Unlike psychopathy, Machiavellianism is a trait linked with a strategic and flexible behavioral profile. Such individuals only engage in antisocial behaviors when the rewards outweigh the risks.

Such individuals, due to their calculating nature, are likely to engage only in crimes that are difficult to detect and hard to punish. This might lead to a predisposition for committing the more complicated forms of corporate crime. Of the three dark triad traits, Machiavellianism is perhaps the most studied when it comes to accounting fraud and secretive types of corporate crime. Machiavellian individuals feel little guilt about their actions because of their cynical worldview. Machiavellian individuals usually have a toxic effect on the ethical tone of a company and are able to convincingly rationalize their illegal or unethical behaviors. However, Machiavellianism is useful in business settings but only when found in moderate degrees. Thus, too much or too little Machiavellianism becomes problematic.

Finally, narcissism is also likely to be linked with corporate crimes in certain cases where overconfidence or ego threat is involved. For example, narcissistic individuals are likely to unrealistically believe that they have superior abilities to others and exaggerate their skill set. These overconfidence errors leave them prone to poor work behavior. Similarly, narcissistic individuals are entirely ego-driven. As a consequence, insults or threats to their superior sense of identity are likely to be met with aggressive responses. Narcissism has been linked with poor supervision, cocksure risk taking, and excessive consumption of valuable resources. It is not that narcissistic individuals are predisposed to commit crimes such as those high in psychopathy, it is simply that they feel entitled to more than their fair share. As a consequence, individuals high in narcissism tend to talk down to others, take advantage of others, and abuse any power given to them. Interestingly, however, narcissistic individuals do tend to get ahead quickly using social charm, are generally well-liked in first encounters, and interview well. However, it is important to note that these benefits fade over time, and the narcissistic individual is eventually seen as tedious and difficult.

Final Thoughts

Corporate crime damages a wide range of individuals ranging from employees, consumers, shareholders, stakeholders, and other members of society, and its impact is far-reaching. Corporate crime is not only financially damaging to a wide

range of individuals, but also erodes basic trust in business, forces expensive and tedious safeguards on legitimate business endeavors, and creates a sense of insecurity and anxiety about business that is detrimental to societal well-being. From a situational perspective, the presence of financial need/pressure, rationalization, and opportunity drives a temptation toward corporate crime. From a dispositional perspective, specific personality traits, such as the dark triad traits, may help identify individuals at high risk for committing such crimes.

CORPORATE PSYCHOPATHS

Corporate psychopaths refer to individuals who are exploitative, manipulative, callous, unethical, opportunistic and who manage to stay out of prison settings. The media and general population have depicted psychopaths as serial murderers, violent gang leaders, and individuals capable of the most treacherous crimes. While psychopaths are more likely to commit such crimes, some of them manage to avoid getting caught or brought into contact with the criminal justice system. Consequently, increasing attention has been paid to psychopaths operating within the workplace. It seems that the attributes that allow these individuals to commit crimes so effortlessly also help them enter organizations and obtain higher management positions. The corporate psychopath may be just as dangerous in the workplace as he or she is elsewhere in society. This entry first defines psychopathy generally and then focuses on corporate psychopathy specifically and discusses its relation to misbehavior and crime in the workplace, including prevention.

Defining Psychopathy

Robert Hare's conception of psychopathy—defined in his instrument, the Psychopathy Checklist-Revised—is widely used to measure psychopathy. According to this measure, psychopathy can be identified based on four underlying factors: (1) *interpersonal factor* (glibness or superficial charm, grandiose sense of self-worth, pathological lying, or conning or manipulative behaviors); (2) *affective factor* (lack of remorse or guilt, shallowness, callousness or a lack of empathy, or a failure to accept responsibility for actions); (3) *lifestyle factor* (need for stimulation and is prone to boredom, parasitic lifestyle, lacks realistic long-term goals, is impulsive, or irresponsible); and (4) *antisocial factor* (poor behavioral controls, early behavior problems, juvenile delinquency, revocation of conditional release, or criminal versatility).

This measure can be used to identify corporate psychopaths who possess the same traits; in fact, while researchers have reported a prevalence rate for psychopathy of about 1% in the general

population, some have found a 4% rate of psychopathy in higher management using the same instrument (the Psychopathy Checklist-Revised). Although psychopaths in the workplace may score as high as psychopaths who are incarcerated on the Psychopathy Checklist-Revised, some have argued that they score higher on interpersonal traits and lower on antisocial traits. However, while much is known about the way psychopaths operate in society, the same is not true for psychopaths in the workplace where more research is needed.

Corporate Psychopathy and Misbehavior in the Workplace

Counterproductive work behaviors have been associated with important costs to organizations and other employees. These behaviors include psychological harassment, fraud, and antisocial behaviors. Not surprisingly, research has identified psychopathy as one of the predictors of counterproductive work behaviors. Psychopathy is associated with interpersonal aggression and is a strong predictor of bullying. In the workplace, psychopathy is associated with workplace harassment and incivility toward coworkers. To psychopathic individuals, others are merely accessories to their personal success; they will not hesitate to claim others' work as their own and discredit others to gain higher management's trust and support. These negative behaviors can lead to lower job satisfaction, lower productivity, and higher rates of employee turnover in teams that include psychopathic individuals. Moreover, as is the case for other types of crimes they perpetrate, psychopathic individuals carry out these harmful behaviors in the workplace without a trace of remorse or guilt.

Corporate Psychopathy and White-Collar Crime

White-collar crime is an understudied concept, perhaps because the impact of these types of crimes is not as immediate and visible as the impact of violent crimes. Indeed, compared with violent crimes such as murder and physical aggression, the marks left by white-collar criminality are far less visible but nonetheless

ravaging. What is clear, however, is that white-collar criminals exploit and defraud organizations and individuals. Companies have been driven to bankruptcy leaving people without jobs and money on which to live or retire. While corporate psychopaths may differ from psychopaths in prison settings by presenting better interpersonal skills to deceive and manipulate others and by having performed fewer criminal acts associated with street violence or general criminality, both are callous individuals who are out to satisfy their own personal needs and who will not hesitate to exploit others to get what they want. Furthermore, some types of white-collar offenders are willing to resort to physical aggression and murder in order to prevent their schemes from being detected.

It is clear that psychopaths' great manipulation skills and their ability to manipulate and deceive others without feelings of guilt and remorse make them the ideal candidates for white-collar crime. In fact, the interpersonal manipulation tactics used by psychopathic individuals to execute fraud schemes (e.g., gaining trust and making promises appealing to the other person such as promises of wealth or success) are the same tactics used in selection interviews to manipulate their way into organizations in the first place.

Corporate Psychopathy: Entering Organizations and Attaining Promotions

Part of what defines psychopathy is superficial charm, a grandiose sense of self-worth, pathological lying, and conning or manipulation. These traits help psychopathic individuals create and use impression management tactics that can influence decision makers in employee selection and promotion processes. Because employee selection is often based solely on an interview, decisions are influenced by well-known biases introduced by candidates such as physical attractiveness (well-dressed, nice haircut), showing low anxiety, praising the interviewer, and self-promotion. Psychopathic individuals are prone to using all of these interview biases; in fact, the constellation of traits forming psychopathy actually makes them masters of manipulation.

Once hired, psychopathic individuals employ tactics to obtain good performance reports and

promotions in order to climb up the corporate ladder. Individuals with psychopathic traits manipulate coworkers and superiors to get what they want. They control their image by flattering people in positions of power, claiming others' work as their own, and blaming others for their own failures. Because promotions are frequently given based on immediate supervisors' and higher managements' impressions of the employee, individuals presenting psychopathic traits are more likely to be promoted. Promotions oftentimes include management responsibilities, placing psychopathic individuals in leadership positions within their organizations. Although they might share traits with good leaders, managers presenting psychopathic traits will eventually cause pain and suffering to their subordinates and promoting these individuals will come at high costs to the organization.

Corporate Psychopathy and Leadership

There are differences between traits related to leadership emergence (being perceived as a leader at first impression) and leadership effectiveness. While extroversion, charisma, low anxiety in stressful situations, being able to make hard decisions and making grandiose promises can be associated with leader emergence, it takes more than this for a leader to be perceived as effective in the long run. In essence, the traits associated with leadership emergence, such as charisma and extroversion, are perceived as a promise of future effectiveness. However, sometimes the traits associated with leader emergence are simply characteristics of individuals presenting dark personalities. Indeed, traits associated with leadership emergence are mostly related to presentation skills (charisma, verbal agility, grandiose vision, and promises) and are also associated with corporate psychopathy. On the other hand, leader effectiveness is measured through the leaders' ability to care for and coach their employees, motivate and mobilize their teams to attain organizational goals, and deal effectively with conflicts when they arise.

Psychopathic individuals would not be able to meet any of these leadership expectations. While psychopathic individuals are perceived as charismatic, creative, and good communicators, they are rated low on management skills and being a team

player. Moreover, supervisors who are scored high on psychopathy by their subordinates are more likely to use abusive leadership behaviors toward them. In fact, psychopathic traits in leaders are associated with lower levels of employee job satisfaction and work motivation and higher levels of employee turnover intentions, job neglect, and work-family conflict. These results suggest that psychopathy might be an underlying factor of abusive leadership, which is associated with great costs to both subordinates and the organization. Although corporate psychopaths may seem like leaders at first sight, in the long run, they will not prove to be good leaders.

While managers are often hired based on their task-oriented skills and presentations skills during interviewing processes, it is their lack of interpersonal skills that get them fired (after having inflicted damage around them). Leader selection processes that take into consideration skills, such as empathy, humility, and conflict resolution, might make it harder for psychopathic individuals to enter organizations and obtain promotions to leadership positions. However, these skills seem to be very low in the hierarchy of traits that selection experts generally seek in a leader; in fact, in many corporate contexts, selection experts are instructed to look for self-assured candidates who display the most charisma and presence and show no sign of emotion, including empathy.

Prevention

Psychopathic individuals have been found responsible for a disproportionate number of violent crimes committed, and there is reason to believe that these numbers could translate to white-collar crimes. While the latter has not received as much attention as violent offenses, white-collar crimes hurt individuals and have serious repercussions for the economy and society in general.

White-collar crimes are not the only avenue taken by corporate psychopaths to hurt others; they also resort to workplace harassment, abusive supervision, and other forms of aggressive behaviors in the workplace. As is the case for white-collar crime, the impact of aggressive behaviors in the workplace is not visible, but it is nonetheless devastating for coworkers and employees.

One way to prevent these individuals from committing white-collar crime or abusing employees is to prevent them from obtaining positions within organizations where they have access to money or power over employees. To do so, organizations can invest in employee selection processes that include structured interviews based on competencies judged essential for the position, psychometric testing, and background checks. However, many organizations may not recognize the full implications and costs of white-collar crime and abusive supervision and thus are not likely to spend money on extensive selection and promotion processes. Furthermore, the common perception that white-collar criminality is a victimless crime can hinder prevention efforts, allowing the presence of psychopathic individuals in the corporate world to proliferate.

CORRECTIONAL AGENCIES

The earliest correctional agencies in the Western world developed almost 900 years ago when King Henry II of England built county jails for the temporary detention of debtors and those who had committed minor offenses. In the 15th century, houses of corrections or workhouses (another English innovation) were aimed at forcing the *idle poor* (i.e., vagrants, beggars, and delinquents) to work off debts while in confinement. The English also used prison hulks, or decommissioned Navy ships, to house convicts while floating at anchor in the Thames River.

In the United States, the first correctional agencies, county jails, developed in the 17th century. In 1818, the Pennsylvania legislature authorized construction of two new prisons, the Western Penitentiary near Pittsburgh and the Eastern State Penitentiary in Philadelphia. The penitentiary concept was designed to isolate miscreants and provide them with a place to do penitence, pastoral counseling, and reasonable discipline that would help them correct antisocial behavior. The Western Penitentiary was completed in 1826 and was in use until demolished in 1880. A new facility was constructed in 1882 and is still in use (the State Correctional Institution at Pittsburgh). The Eastern State Penitentiary was finished by 1829 and became a model for prisons in a number of states and in several European countries. The Commonwealth of Pennsylvania closed the facility in 1971, 142 years after it admitted its first inmate.

From these early efforts, a vast complex of correctional agencies has emerged across the United States. These range across security levels from probation in the community to super maximum security prisons. Between these two extremes, there are many different kinds of institutions with varying levels of security and differing types of confinement. This entry discusses these various correctional agencies in some detail from the least secure to the most.

Community Correctional Agencies

The largest correctional agencies are the more than 2,000 state- or county-run probation offices

entrusted with supervising people convicted of both misdemeanors and felonies, while they remain in the community. These agencies employ more than 100,000 probation officers and other administrative staff. The first use of probation began with the volunteer services of John Augustus in Massachusetts, a local businessman who in 1841 accepted his first probation client. Over an 18-year period, Augustus bailed out and supervised approximately 2,000 probationers, helping them get jobs and establishing themselves in the community. Recognizing Augustus's achievements, Massachusetts formalized probation in 1859, a year after his death, creating the nation's first paid probation officers. Based on the model that Augustus pioneered, the practice of probation spreads rapidly around the country.

Probation allows an offender to remain in the community for the duration of his or her sentence under supervision by an officer of the court. While on probation, the offender is required to comply with whatever conditions and rules the court imposes. Probation can be a standalone sentence but typically involves suspension of a term of incarceration in return for the promise of good behavior in the community under the supervision of a probation officer. If the rules are violated or the probationer commits another offense, probation may be revoked, which means that the contract is terminated and the original sentence of imprisonment is enforced. While on probation, clients are typically enrolled in social service programs to help them deal with the problems that resulted in their criminal convictions. This might include anger management, drug counseling, education programs, and the like.

The United States has approximately 2,000 adult probation agencies. More than half are associated with a state-level agency. State-run probation allows uniform standards of policy making, recruitment, training, and personnel management to be applied to probation practices throughout the state. Coordination with the state department of corrections and with the parole service is also facilitated by state-run, or centralized, probation models. In the remaining states, probation is primarily a local responsibility. In these jurisdictions, state offices are accountable only for providing financial support, setting standards, and arranging training courses.

About 30 states combine probation and parole supervision into a single agency. Since both probation and parole have the same set of goals and the same skills are required for the supervision of offenders, a combined system conserves scarce resources, requiring only one office, one set of directives, and one supervisory hierarchy.

In addition to local and state-run agencies, federal courts administer probation services. The U.S. Probation and Pretrial Services division provides probation and pretrial services to the U.S. District Courts. U.S. District Court judges control federal probation services, but the probation division's administrative offices handle the recruitment and training of personnel.

In some jurisdictions, the private sector also administers probation agencies. The private supervision of misdemeanor probationers was first implemented in Florida in the 1970s under the supervision of the Salvation Army Misdemeanor Program. At its peak, Salvation Army Misdemeanor Program employed 200 counselors in 37 counties and supervised 14,000 clients a month. As of 2018, probation agencies in about 10 states (e.g., Georgia, Mississippi, Tennessee, Florida, Alabama, Connecticut) still use privatized probation services for low-risk offenders.

Intermediate Sanctions

In addition to traditional services, modern probation agencies dispense a range of *intermediate sanctions*. These can include intensive probation, financial restitution, community service, house arrest, and electronic monitoring. Intermediate sanctions allow judges to match the severity of punishment with the severity of the crime. They are more intrusive than traditional probation but less invasive and stigmatizing than an incarceration sentence.

Intermediate sanctions fall along a continuum ranging from the least intrusive (e.g., fines, community service) to the most intrusive (e.g., house arrest, electronic monitoring, placement in a residential community-based facility). It is also possible to combine a variety of intermediate sanctions into a single sentence. Clients in an intensive probation program may be, for example, assigned to house arrest and placed on electronic monitoring. Other offenders may be sentenced to

a short period of confinement before they begin their probation sentence. This is referred to as *split sentencing* or *shock probation* and is intended to *shock* offenders into conformity after briefly experiencing prison life. *Residential confinement* is a form of confinement that takes place prior to imprisonment (halfway-in) or following imprisonment (halfway-back). Boot camp programs are also perceived as intermediate sanctions.

Some probation agencies operate group homes, halfway houses, and work release programs that provide residential services for probationers who are allowed to live in the community while receiving treatment services ranging from drug counseling to cognitive behavior therapy. These facilities include both governmental and privately administered programs. One popular approach is referred to as the therapeutic community, a therapy program that aims to refocus or resocialize the resident and uses the program's entire community (including other residents and staff) as active components of treatment. Residents learn the techniques needed to develop personal responsibility, which can eventually lead them to socially productive lives.

County Correctional Agencies: Jails

Jails had their origin in medieval England, where they were initially conceived of as a place for detaining suspected offenders until they could be tried and punished. Over time, jails gradually evolved to serve the dual purposes of detention and punishment. Early jails were catchall institutions that held not only criminal offenders awaiting trial but also vagabonds, debtors, the mentally ill, and assorted others. Inmates were not segregated by age, gender, or seriousness of offense. The most common reason for locking people up in jails was unpaid debts, a practice that guaranteed the poor could never earn the money they owed.

The first colonial jails were established in Massachusetts and Virginia, but it was Pennsylvania jails, established by reformer William Penn in the 17th century, that later became the model for other states. In 1773, the Walnut Street Jail was constructed in Philadelphia. In the Walnut Street Jail, prisoners were employed at hard labor in the institution and taken out in public during the day to repair and clean streets and highways. The

assumption was that hard work would build discipline and aid reform.

The modern local county jail is a correctional agency with a dual purpose. First, it is used to detain people before trial who cannot make or afford bail or those who fall under mandatory arrest statutes who cannot be released in order to protect their safety or the safety of others. Someone arrested for driving while intoxicated, for example, might remain overnight or longer in a jail for his or her protection, as well as the protection of the general public. Jails also hold convicted inmates sentenced to short terms (generally a year or less) for petty offenses, such as simple assault or petit larceny. Jails are usually administered by the county sheriff but are sometimes managed on a regional basis or, in a few cases, by the state or federal government.

There are a number of models used to administer jail agencies. *Some* cities and counties separate detention and incarceration functions. In New Hampshire and Massachusetts, for example, a house of corrections holds convicted misdemeanants and a county jail holds pretrial detainees. Four states have full operational responsibility for jails; these include Connecticut, Delaware, Rhode Island, Vermont, and except for five locally operated jails, Alaska.

A widely used alternative to local or state control is regional or multicounty arrangements. Kentucky, Virginia, West Virginia, North Dakota, South Dakota, Nebraska, and Kansas were the first states to adopt regional jails. This arrangement typically exists when a jurisdiction with an adequate jail is willing to contract with neighboring cities and counties to house prisoners on a per diem basis, or when a group of local governments decides that no existing facility is adequate and chooses to build a new regional jail or *detention center*. Local governments may decide to specialize and house different populations, such as juveniles, females, pretrial detainees, or convicted felons awaiting transportation to state prisons.

Some states provide subsidies to county facilities. Almost 60% of states provide technical assistance to local governments to address jail issues, and about 50% provide training for jail personnel. In addition, some subsidy programs assist jails in complying with state standards and in making capital improvements ordered by courts.

There is a wide range of jail facilities. Large urban centers routinely maintain jails holding more than 1,000 inmates. In contrast, small, rural jails might hold fewer than 50 inmates. Each has its own set of challenges. Rural jails, for example, typically provide few programs, rarely have adequate staffing, and are less likely to have satisfactory suicide prevention policies in place. In contrast, urban jails must deal with overcrowding, violence, inmate sexual victimization, contraband being brought into the jail, and even staff corruption.

As of June 2016, about 740,000 inmates were being held in jails, most of whom are pretrial detainees held in the nation's largest counties. After decades of steep increases in U.S. jail populations, inmate levels have begun to stabilize and even decline. Jail incarceration rate declined from a peak of 259 inmates per 100,000 U.S. residents at midyear 2007 to 229 per 100,000 at midyear 2016.

Secure Correctional Agencies: Prisons

Secure correctional agencies oversee the intake, incarceration, and release of the more than 1.5 million men and women sentenced to a felony prison term. There are 50 separate state departments of corrections as well as one for the District of Columbia. The systems are difficult to compare and evaluate because of differences in ideology, structure, and programs. The quality of previous correctional leaders, the resources available, and the volume of inmates has largely shaped what takes place within each independent correctional agency.

In addition to state prisons, The Federal Bureau of Prisons oversees more than 120 correctional institutions (in addition to 13 privately operated facilities), six regional offices, a central office in Washington, DC, two staff training centers, and 26 community corrections offices. The Federal Bureau of Prisons is responsible for the custody and care of more than 210,000 federal offenders, of whom 81% are confined in bureau-operated correctional institutions or detention centers. The remaining offenders are confined through agreements with state and local governments or through contracts with privately operated community correctional centers, detention centers, and juvenile facilities.

Types of Prison Facilities

Both federal and state agencies maintain a variety of correctional facilities. Minimum-security prisons, medium-security prisons, maximum-security prisons, and supermax prisons are described below.

Minimum-Security Prisons

Minimum-security prisons house nondangerous and nonviolent offenders. They have relaxed perimeter security, sometimes without fences or any other form of external security. Inmates work, go to school, and take vocational classes. They are often permitted to work at outside jobs, such as on road crews or doing exterior maintenance. These facilities have generous visitation policies with contact visitation, sometimes including even short home furloughs. They offer a safer environment for both staff and inmates than do other types of prisons.

Medium-Security Prisons

Medium-security prisons house more dangerous or repeat offenders. They are typically built with single or double fencing and have guarded towers or closed-circuit television monitoring, sally-port entrances, and zonal security systems to control inmate movement within the institution. In medium-security prisons, the emphasis is on controlled access to programs and internal facilities. Prisoners assigned to medium custody can be locked down in emergencies, but it is expected that they will participate in industrial and educational activities within the prison. The rationale behind medium-security facilities is that a good deal of freedom of movement and the availability of programs within a technologically secured perimeter can help inmates work toward a successful release.

Maximum-Security Prisons

Maximum-security prisons house dangerous and repeat offenders. They are generally large and imposing physical structures. Some of the older maximum-security facilities in the United States are surrounded by stone walls with guard towers at strategic places. These walls may be 25 or more

feet high. Newer maximum-security facilities, however, tend to be surrounded by several fences (including some that may be electrified) because of the expense of stone walls.

Supermax Prisons

State and federal correctional agencies have created the so-called supermax prisons to house their most dangerous inmates. More than 40 states have either built supermax prisons or added high-security units to existing facilities to contain problem prisoners. More than 25,000 male and female inmates are now housed in 57 supermax facilities across the nation. These inmates include antiabortion activist and “Olympic Park Bomber” Eric Rudolph and terrorists such as Richard Reid, Terry Nichols, Zacarias Moussaoui, and Boston Marathon bomber Dzhokhar Tsarnaev.

The most famous supermax prison is the 484-bed United States Penitentiary, Administrative Maximum Facility in Florence, CO. Administrative Maximum Facility has the most sophisticated security measures in the United States, including 168 video cameras and 1,400 electronically controlled gates. Inside the cells, all furniture is immovable and virtually indestructible. Beds, desks, and television stands are made of cement. All potential weapons, including toilet seats, toilet handles, and soap dishes, have been removed. The cement walls are capable of withstanding 5,000 pounds of pressure, and steel bars are placed so that they crisscross every 8 in. inside the walls of the institution. Cells are angled so that prisoners can neither see each other nor the outside scenery. This cuts down on communication and denies inmates a sense of location, to prevent escapes.

CORRECTIONAL BOOT CAMPS

The term *correctional boot camps* refers to correctional programs that involve a relatively short period of placement (90–180 days) in a setting similar in environment, attitude, and activities to military basic training or boot camp. The offenders, often referred to as *cadets*, involved in a correctional boot camp program are required to participate in military-style drills and physical activities and are required to comport themselves in a manner similar to the military (e.g., responding to questions with a vigorous “Yes, Sir!” or “No, Sir!”). Correctional boot camp cadets typically are youthful, nonviolent offenders with few prior convictions.

Advocates of correctional boot camps claimed these programs are effective in reducing subsequent offending and helped reduce the prison population by being an alternative to imprisonment. In a roughly 25-year period starting in the early 1980s, correctional boot camps emerged, became common, and then fell into obscurity. The rise of correctional boot camps is largely explained by their fit with *tough on crime* movement of the 1980s and 1990s, and their decline was fueled by mounting evidence of their ineffectiveness in achieving their stated goals as well as numerous instances of egregious cadet abuse.

Common Elements of Correctional Boot Camps

Correctional boot camps share many common elements. Most notably, all boot camps have an atmosphere simulating military basic training. The housing units typically resemble military barracks (not prison or jail cells). Cadets and correctional officers wear military-style uniforms. Correctional officers are given military ranks (e.g., sergeant,

major). Cadets are organized into groups typically called *platoons*. Members in the same platoon live and eat together, complete military exercises and drills together, and graduate together.

Correctional boot camps are commonly organized into three or more phases. Program activities vary by phase. Typically, early phases involve higher levels of exercise and military drills and later phases involve higher levels of community service (e.g., picking up trash) and treatment programming. In all phases, cadets are required to wake up early (5 a.m.) and engage in various activities throughout the day; there is little to no time for unstructured activities. The structured activities involve exercise, military drills, completing obstacle courses, community service, educational programs, vocational programs, and treatment programs. The typical correctional boot camp program is intended to last 90–180 days, but the actual length of confinement is often longer due to in-program misbehavior. Minor misbehavior is disciplined using physical exercises such as push-ups and verbal reprimands. Repeated and serious misbehavior typically is met with the removal of valued privileges and/or program expulsion. Expelled cadets most often are moved to traditional correctional institutions (i.e., jails, prisons) to serve a longer period of confinement. Successful cadets, on the other hand, are celebrated with a graduation ceremony for each platoon.

Most correctional boot camps have eligibility criteria that limit those involved to youthful offenders with relatively minor criminal history. The physical vigor of boot camps leads to older offenders and offenders with serious medical programs being ineligible for boot camps. Thus, the typical correctional boot camp cadet is younger than 35 years of age and many, if not the majority, are under age 25. Furthermore, correctional boot camp programs are used in most jurisdictions as an intermediate sanction in between probation and prison, suited for nonviolent offenders with a limited number of prior convictions. This population is viewed as being amenable to boot camps, as boot camp advocates contend that these offenders will be deterred by the harsh environment of correctional boot camps and the military discipline at the heart of each correctional boot camp will instill self-discipline in these wayward youth.

In addition to the pseudo-military atmosphere, the vast majority of correctional boot camps

incorporated rehabilitative programming. In fact, correctional boot camps appear to have evolved toward greater use of rehabilitative programming over time. The earliest correctional boot camps, which were introduced in 1983, had little to no rehabilitative program other than educational programs. By contrast, later correctional boot camps included considerable rehabilitative programs, especially drug treatment.

The Proliferation of Boot Camps

The first modern correctional boot camp appeared in the United States in 1983, when two correctional boot camps opened (one in Oklahoma and one in Georgia). From there, correctional boot camps spread rapidly. Ten years later, the number of correctional boot camps rose to at least 59; and in 1995, there were at least 120 correctional boot camps operating in the United States.

The growth of correctional boot camps was driven by many factors; however, three factors appear most prominent. First, the policies and philosophy guiding sentencing and corrections in this era changed to a *tough on crime* approach. The U.S. prison population grew at unprecedented rates in the 1980s and 1990s, as a direct result of these policy changes. This glut of prisoners strained the capacity of existing prisons and created a need for alternatives to prison. Second, correctional boot camps with their strict, militaristic atmosphere were emblematic of the tough on crime approach. Congress blessed the boot camp model by providing federal funds to jurisdictions to implement correctional boot camp programs in the Violent Crime Control and Law Enforcement Act of 1994. Third, proponents of correctional boot camps successfully argued that correctional boot camps not only provided an intermediate sanction for offenders too serious to be placed on probation and too marginal to be imprisoned but also reduced prison populations and prison costs by diverting marginal offenders from strained prisons.

Research Concerning Correctional Boot Camps

The growth in the number of correctional boot camps largely preceded rigorous research examining the effectiveness of correctional boot camps to

control prison populations and reduce recidivism. In time, however, a voluminous body of research focused on these issues, particularly correctional boot camp's effect on recidivism. This body of research also examined the effect of correctional boot camps on prisoner adjustment to confinement, as boot camp critics contended that the confrontational, punitive environments of correctional boot camps would have harmful psychological effects on youthful offenders, especially those with histories of abuse.

Succinctly stated, the research does not support the contention that correctional boot camps reduce recidivism. A host of studies evaluated correctional boot camp's effects on recidivism. In 2005, David B. Wilson, Doris L. MacKenzie, and Fawn Ngo Mitchall synthesized these studies using meta-analytic techniques. The overwhelming majority of these evaluations found no meaningful or statistically significant differences in the recidivism rates of correctional boot camp participants and similar offenders who were sentenced to traditional sanctions. Thus, Wilson and colleagues concluded that correctional boot camps are ineffective in reducing recidivism—correctional boot camp participation had no measurable effect on recidivism in either direction. However, correctional boot camps that incorporated greater levels of rehabilitative treatment programming did exhibit lower levels of recidivism among their cadets than among offenders sentenced to traditional sanctions.

The question becomes: Why are correctional boot camps ineffective in reducing recidivism? The evidence suggests that perhaps this ineffectiveness is due to the fact that boot camp participants do not find the correctional boot camp atmosphere particularly onerous. Contrary to boot camp advocates' claim that correctional boot camps' harsh, Spartan environments would be perceived as grueling and objectionable and as a result deter subsequent offending, the empirical evidence indicates that boot camp participants have more favorable perceptions of their correctional experience in comparison to offenders confined in traditional facilities. In all likelihood, the favorable perceptions of correctional boot camps are attributable to the fact that correctional boot camps solve one of the central problems of confinement—boredom. The heavily structured

schedule of correctional boot camps permits little idle time, and thus boredom is minimized. On the other hand, critics of the boot camp model contend that correctional boot camps are ineffective because they do not offer sufficient treatment programming aimed at the risk factors known to predict recidivism. The empirical research also contradicts this explanation, in that, on average, correctional boot camps had as much rehabilitative programming as traditional facilities. Taken together, these findings suggest that correctional boot camps are no more effective than traditional kinds of confinement because boot camp participants do not perceive the correctional boot camp environment as especially onerous and boot camp participants receive comparable levels of rehabilitative treatment as offenders confined in traditional facilities.

The research assessing correctional boot camps' purported ability to reduce prison population is more limited. Yet, this research indicates that correctional boot camps, like other intermediate sanctions, do not reduce prison populations. The reason for this failure to reduce prison population is simple—most offenders eventually sentenced to correctional boot camps would have been sentenced to some form of probation had correctional boot camps not existed. Thus, correctional boot camps are more likely to *widen the net* by exposing those who would have been sentenced to probation, rather than divert those who would have been sentenced to prison (or longer jail sentences). Moreover, a considerable portion of those committed to a correctional boot camp program is eventually expelled for noncompliance, which typically results in these offenders being placed in secure confinement for longer periods than they would have served in the correctional boot camp program. As a result of these two factors, the research indicates that correctional boot camps have minimal effects on prison populations or prison costs.

A sizable body of research also examines offender adjustment to correctional boot camps in comparison with offender adjustment in other kinds of correctional facilities. Opponents of correctional boot camps contend that the environments of boot camps lack the supportive care necessary to rehabilitate troubled youth, and the confrontational atmosphere of boot camps may

actually harm youth with histories of neglect and/or abuse. The boot camp adjustment knowledge base indicates that the majority of boot camp participants quickly adjust to the boot camp environment; however, some participants have considerable difficulty with this adjustment. Consistent with the contentions of boot camp critics, those at most risk of adjustment problems are those offenders with histories of abuse. Yet, even among offenders without such histories, a minority of offenders has more problems adjusting to correctional boot camps than do offenders sentenced to traditional institutions. These offenders are unwilling or unable to comply with correctional boot camps' rules and as a result run afoul of correctional boot camps' strict code of conduct.

The empirical research examining correctional boot camps finds that these correctional programs are neither as effective as their proponents claim nor as harmful as their critics claim. Correctional boot camps do not reduce the recidivism as their proponents claim, but they do not increase recidivism as their critics sometimes assert. Correctional boot camps do not reduce prison populations or costs, yet they most likely do not increase populations or costs. Likewise, correctional boot camps do not affect adjustment for the majority of offenders.

The Demise of Boot Camps

Since the late 1990s, the number of correctional boot camps in the United States has dropped dramatically. For example, between 1995 and 2000, one quarter of all correctional boot camps were closed. This contraction in the number of boot camps accelerated in the new millennium. In 2018, only a small number of boot camps remained in operation.

Correctional boot camps' demise is largely explained by a dramatic erosion in their political support. Correctional boot camps once received considerable bipartisan political support. This support diminished as evidence mounted of correctional boot camps' ineffectiveness in reducing prison populations and recidivism. Furthermore, the erosion in political support for correctional boot camps was accelerated by reports of offender abuse at the hands of correctional staff.

Several prominent cases of offender abuse garnered media attention and apparently sparked a

backlash against correctional boot camps. Youthful offenders in several states died due to being pushed passed their physical limits and/or being deprived of access to medical attention. Perhaps the most dramatic and prominent case of offender abuse at a boot camp was the videotaped death of Martin Lee Anderson. Anderson was a 14-year-old boy, who was confined at one of Florida's numerous boot camps. On his first day in the boot camp, he was forced to engage in physical activities including a run. When he complained of fatigue and shortness of breath, correctional officers coerced Anderson to continue his exercise by using force—all of which was captured on videotape. Anderson collapsed, and 1 day after being admitted to the boot camp, he died. Anderson's death combined with numerous preexisting complaints of abuse were a direct cause of the demise of correctional boot camps in Florida, all of which were ordered closed. Thus, Florida, once a state with numerous correctional boot camps for juvenile offenders, has none in 2018. Florida is a microcosm of a national retreat away from correctional boot camps, which eventually resulted in only a handful of correctional boot camps remaining in operation.

CORRECTIONAL MANAGEMENT

Correctional management can be defined as the leadership and governance of a prison or jail facility. Those who are responsible for the confinement of offenders are charged with operating safe and humane facilities that protect the public, staff, and inmates of the institution. The chief executive officer (CEO), often referred to as the warden or superintendent, and his or her staff are responsible for many varied activities. They are responsible for providing all services one would expect: food, medical care, maintenance services, jobs, recreational facilities, laundry, as well as the provision of a safe and clean environment. Add to this list the provision of programs that provide inmates an opportunity to improve themselves for their future return to their home community: education options that range from adult basic remedial schooling to GED (General Educational Development) programs as well as vocational training offerings that assist offenders as they improve their employability for the future. In addition, management often offers specific programs such as anger management, drug treatment, and parenting classes.

The general environment of prisons and jails is inherently negative, and staff are tasked with controlling the environment, keeping order, and providing the appropriate level of services for the correctional population. Order stems from controlling violence, ensuring a calm environment, and instilling a sense of fairness in how the institution is managed. Given that offenders may challenge authority, correctional leaders ensure that rules are followed and courtesies extended to and from inmates. Correctional leadership and management are responsible for accomplishing all of these tasks—control, supervision, and accountability—while creating an environment in which staff members manage the inmate population in a professional and positive manner.

Diverse Inmate Populations

One challenge for those charged with managing correctional populations today is the variety of inmate needs that must be met in a safe and constitutional manner. These offender issues range from behavioral problems to geriatric care, and

each inmate has specific custodial and care requirements.

Institutional security begins with an inmate classification program. Nearly all correctional systems offer separate institutions for specific security needs (minimum, medium, and high security), specific medical and mental health support, and for offenders with special needs. A professional, empirically based classification system separates inmates according to needs and allows the correctional administrators to designate each to the proper facility designed for the offender's specific requirements.

Prisoners who are not able to behave at lower security-level institutions may be moved to higher security facilities within the correctional system. In addition, convicted offenders who have demonstrated a history of violence, in past offenses or in their current offense behavior, or those who act out and present disciplinary challenges are typically placed in more secure institutions. Correctional staff at these higher security institutions implement not only additional security but also increased supervision of inmates.

Medical and mental health issues are a major consideration in today's prison and jail systems. Inmates with physical infirmities must receive adequate care while they are confined. In addition, an increasing number of convicted offenders are classified as special needs inmates; these men and women have various mobility, vision, and hearing impairments, and correctional managers must make reasonable accommodations for them, by both law and policy.

Prison and jail populations also contain large numbers of inmates with mental health concerns. Serious mental illness and individuals with pervasive personality disorders often present with emergent issues that require significant staff time and concomitant cost. Correctional mental health professionals and line staff members must be able to discern those who are merely behaving badly from those with serious mental health concerns, and all staff must be trained to interact professionally with those with mental illness. Such inmates, regardless of the security level of the facility, must be provided with a reasonable level of psychiatric and psychological care.

The varied correctional strategies necessitated by the diversity of inmate needs requires an

ongoing effort on the part of institution leaders and professionals at all levels of the facilities.

Correctional Leadership

As in every organization, public or private, the CEO and senior leadership staff shape the difference between mediocrity and a great place to work. The leader's ability to set the vision, establish the tone, and communicate with employees is a key factor in an agency's success. Multiple researchers and criminal justice practitioners have documented the simple concept that the quality of any prison and jail operation is directly attributable to the quality of correctional leadership. Succinctly put, excellence in leadership in the institutional setting results in a safe, secure, more effective, and humane facility for the inmates to live and staff to work.

Effective leaders cultivate a sense of pride in their correctional staff. Their employees are well trained, are supported by supervisory personnel, and believe they have chosen a career in public service where their work makes a difference in the lives of inmates and the protection of the public. Those involved in correctional leadership must consistently keep the vision and mission of these goals in front of staff at all levels of management and the line staff.

Correctional institutions each have a unique environment and the quality of institutional operations varies across the United States and the world. Yet facilities that are seen by their constituents and peers as first-rate operations consistently rank high in terms of morale, professionalism, and proficiency. In other words, leaders in this field ensure that their prisons and jails provide good order and rank high in terms of safety, sanitation, and level of service.

Correctional Philosophy

The United States has a legacy of punishment that dates to its colonial past and beyond to its European heritage. The concept of vengeance or *just desserts* makes up a large part of Americans' collective expectations of federal, state, and local justice systems. Most Americans agree that the country's prisons and jails are intended to punish those who have harmed other citizens or the

government. How society punishes has evolved over the years and has been shaped by judicial interpretations of the Constitution of the United States.

The idea of rehabilitation has been introduced over the last 200+ years and reflects the idea that correctional institutions must offer inmates the opportunity to change their behavior and return to society as law-abiding citizens. While criminal careers vary and do not follow predictable patterns, many believe that correctional managers have an obligation to offer a new future to convicted offenders who wish to take advantage of institutional programs that offer help.

The effective correctional leader today must have the ability to merge these two competing concepts of controlling inmates as well as helping them. These philosophies of correctional leadership are not mutually exclusive and must be offered to all offenders as institutional staff guide them throughout their confinement. Correctional staff must consistently point incarcerated individuals toward their eventual release to their home community. Successful prison and jail leaders manage safe and secure facilities yet merge such control with the concepts of hope and change. Effective correctional leaders value both philosophies and ensure their mid-managers and line staff members understand the importance of each.

Interpersonal Relations

The CEO of a correctional institution must be able to communicate effectively and reasonably with many entities: staff, inmates, union officials, members of the community, the media, the state and federal courts, and elected representatives at all levels of government. Performance excellence in any public, nonprofit, or for-profit organization requires the ability to listen, respond appropriately, and lead in the face of adversity. Whether dealing with inmate or staff grievances, employee meetings, or interviews from an interested reporter, the institutional leader must be knowledgeable of all local operations and able to explain the importance of the subject under discussion. Moral leadership is always required, but the CEO must also understand the history and dynamic behind the issue under discussion.

Correctional leaders must grasp any issue from the vantage point of all parties and have the ability to empathize with another point of view. Nevertheless, leadership demands that decisions be made that are appropriate for the safety and security of the public, the inmates, and the staff of the facility.

Strategic Planning

Effective strategic planning is a necessity, and correctional staff members look to the senior executives for direction and support. Senior managers and their line staff must establish and reinforce the mission and vision for the overall agency and each individual facility. Once the operational philosophy is established, personnel at all levels are then invited to participate in the goal-setting process to determine the best means of accomplishing the priorities of the organization. Once this planning effort has been completed, it is much easier for senior executives to ask for and receive buy in from all personnel working within the agency.

For training and orientation purposes necessary to proactive correctional management, all new staff must understand how their responsibilities are critical to the success of the mission of the institutional program. It is extremely important for a new correctional officer to understand why his or her tasks are important aspects of public safety. In other words, even mundane tasks associated with good inmate accountability is more than *completing the count* for evening lockdown, it is pivotal to the precepts of pride and efficiency in one's work. Daily tasks that are done well become key to professional behavior and good morale—and effective custody procedures can create public confidence in the agency. All of these positive outcomes begin with professional managers involving staff at all levels in developing a definition of the mission and planning the activities that will help plan the path to successful outcomes.

Additional Influences

Correctional agencies do not exist in a vacuum but operate in a complicated legal and political milieu. Historically, judiciary and elected officials generally deferred correctional issues to the penal experts managing the institutions. Since the mid-1970s, however, judges and elected leaders have become

more involved in correctional issues such as the conditions of confinement, inmate medical care, quality of food and sanitation, and overcrowding. Judges may even impose judicial oversight orders, whereby they essentially *take-over* some or all of the operational responsibilities for institution management.

Elected officials have also become engaged in correctional oversight. Some have demanded changes within institutions, both to save money and to garner the reputation of being tough on crime and criminals. A consequence of such external attention has been harsher outcomes such as no parole, mandatory minimum sentences, and the national expansion of the numbers of Americans confined. Some politicians have even ventured into the arena of determining what programs and activities correctional staff may offer to the thousands of inmates incarcerated in various facilities across the nation.

The media—national and local print and electronic media—have a profound impact on how prison and jail administrators do their job. There is a critical interplay between the press and the criminal justice systems in the United States. Effective penal administrators understand this relationship and provide the opportunity for an open and honest exchange of information with the members of the fourth estate.

Final Thoughts

In the United States, confinement has become the primary and expected punishment for criminal behavior, and the numbers of people confined in federal, state, and local correctional institutions have become immense. Correctional management is a complex task that requires knowledge ranging from security requirements and procedures, to safety requirements, to developing positive relations with neighbors that live near a penal institution. In other words, many varied tasks are involved in this field, and successful and professional management of the nation's confinement of those convicted of violating the law relies on effective leadership.

CORRECTIONAL OFFICER STRESS

The position of correctional officer is unique in many ways. Staff are accountable for supervising an often unwilling, hostile, and even violent population, 24 hr/7 days a week. Correctional officers are responsible for the care, custody, and control of inmates, which ultimately determines the success or failure of a correctional institution. Daily contact with offenders who have antisocial and antiauthoritative attitudes, who can be uncooperative and manipulative, who display mental and physical health problems, who participate in sexual deviancy, and who can be physically violent at any time creates an environment that is conducive to not only danger but also high anxiety and stress for correctional staff. This entry examines the unique conditions that lead to increased stress for correctional officers and its effects on the quality of life of the officer, experience of the inmates, and function of the institution as a whole. The entry

also provides suggestions for alleviating stress on both the institutional and individual levels.

What Is Stress?

Stress typically refers to nonspecific responses of the body to any demand for change. Sometimes stress is seen in a positive light, as a force that leads to higher performance and productivity; however, most of the research has focused on the negative connotation, where stress triggers undesirable outcomes. The two major dimensions of stress are stimuli and responses. Stimuli (also called *stressors*) are conditions that place excessive or unusual demands on a person and are capable of producing discomfort. Responses occur after short- or long-term exposure to stressors and can be physiological, psychological, cognitive, behavioral, affective, and/or emotional.

Correctional Officer Stressors

Researchers have found that workplace factors (e.g., role stress, job dangerousness, work–family conflict) influence stress levels. Role stress is defined as strain and conflict resulting from job roles with conflicting or unclear expectations. For correctional officers, in particular, role stress can occur around the organizational structure of correctional institutions which tends to be paramilitary, authoritarian, and sometimes hostile. Typically, staff are expected to follow orders without question, and policy and procedure decisions are made from the top down. Too often in this hierarchical administrative structure, correctional officers, who work daily with the inmate population, are the least likely to be consulted about policy changes directly affecting their duties. This can create feelings of powerlessness as a worker. These feelings can be compounded by a perceived lack of support by supervisors who can exacerbate job demands by devaluing an employee's sense of worth and value to the organization. Lack of supervisor support also increases role conflict (compliance with one command makes compliance with another difficult), role ambiguity (lack of information of duties and responsibilities of a job or task), and role overload (requiring too many tasks).

Due to the nature of corrections, job dangerousness (i.e., perceptions related to feeling unsafe

or fearing physical injury) is also a stress factor. Correctional officers work daily under constant threat of violence, which, over time, weighs heavily on an officer. Even though actual injury may not happen frequently, the perceived risk is still present. For example, the loss of institutional control during riots makes this the most dangerous situation because correctional officers can mentally picture the potential for injury and even death. Although it varies among individuals, the fear of victimization becomes a powerful stressor. Like role stress, the lack of input in decision-making can increase the sense of powerlessness and loss of control, which magnifies the perception of job dangerousness.

Correctional institutions are driven by massive amounts of rules and regulations that govern the behavior of workers. Referred to in the literature as *formalization*, the intent of policies, at least in theory, is to reduce uncertainty within the workplace, but if they are unclear or excessively cumbersome, the policies often result in frustration and become a hindrance to worker performance. The limited research points out that greater organizational formalization is related to higher perceived job dangerousness, indicating that too many directives have a negative effect on correctional officers. Intuitively, the more time officers spend daily in contact with inmates, the greater they perceive their job as dangerous. Finally, role strain (i.e., the stress from incompatible or inconsistent expectations and obligations) increases correctional officers' perceived job dangerousness.

Another stressor identified in the literature is work–family conflict, which means work issues can cause conflict at home or home issues can cause conflict at work. There are three dimensions of work on family conflict: time based, whereby time demands from work and work scheduling interfere with home life; strain based, which occurs when the demands and tensions from work negatively impact the quality of life, causing strain and conflict at home; and behavior based, with incompatible work and home roles causing conflict. Correctional work demands availability 24 hr/7 days a week (time based); exposes staff to violence, fear, and hostility on a day-to-day basis (strain based); and expects authority and control (behavior based), all of which are not conducive

to a peaceful, warm, and nurturing home life. Studies show that work–family conflict can lead to higher levels of work stress for correctional officers.

The perception of risk has also been identified as a form of trauma, which elevates the level of stress. Primary traumatic stress occurs when an officer is actually involved in a dangerous incident (e.g., intervening in a fight, discovering a suicide), whereas secondary or indirect trauma is the constant exposure to human suffering, such as observing fights, reading graphic police reports or presentence reports, and hearing about sexual deviance that may include child victims. Research has indicated that this constant exposure contributes to a slow change in how correctional staff view the world. For example, officers may become more cynical and lose empathy and trust for others.

Negative Responses to Stress

One result of stress is job burnout (i.e., a state of fatigue or frustration due to excessive work demands). This chronic strain results in the gradual loss of caring about the people they work with and is most noted among individuals who do *people work*. There are three dimensions of burnout: emotional exhaustion, depersonalization, and a reduced sense of accomplishment. Emotional exhaustion refers to feeling emotionally drained and fatigued at work. Depersonalization is treating others in an impersonal and callous way. A reduced sense of accomplishment is the feeling of not being productive or not having any meaningful impact on others. The research generally supports the link between working in a correctional institution and job burnout. Workplace factors associated with burnout include role stress, role ambiguity, role overload, work–family conflict, lack of supervisor trust, and lack of supervisor support. The findings link burnout to a variety of negative psychological and physical conditions, such as depression, increased levels of post-traumatic stress, decreased physical health, lower job morale, increased use of sick leave, more frequent thoughts of leaving the job, more distanced relationships with coworkers and supervisors, and more punitive attitudes toward inmates.

Job satisfaction, an emotional response related to whether employees like their job, is also

affected by stress. For the most part, positive experiences at work increase job satisfaction, resulting in more positive outcomes. For correctional officers, higher job satisfaction leads to greater support for rehabilitation, greater compliance with organizational rules, and an increased satisfaction with life overall. Stress is considered a negative workplace factor and leads to lower job satisfaction. Overall, lower job satisfaction has been linked to burnout, absenteeism, turnover intent, and lower job performance.

Stress also affects organizational commitment (i.e., the bond between an employee and the organization for which he or she works). The literature has identified three dimensions of this concept: affective commitment, normative (moral) commitment, and continuance commitment. Affective commitment is a positive emotional bond whereby the employee has shared interests and values with the organization. In other words, they identify with the organization and take pride in being part of the organization. It is seen as a psychological bond because the bond of the employee to the organization is voluntary. Normative commitment or moral commitment argues that the bond between an employee and the organization is based on expectation, loyalty, or a moral obligation. Individuals act in a way that may not be to their own personal benefit but believe to be the right thing to do for the organization. Finally, continuance commitment is a bond based on investments made with the organization over time. A person is committed to the organization due to pay, benefits, and pensions and not because they identify with the agency. Research has found that job stress was a significant predictor of lower organizational commitment, in that it was associated with lower affective commitment and higher continuance commitment (i.e., a bond based on a perceived inability to leave). Thus, correctional officers exposed to stress not only have a reduced connection with the values and interests of the organization, but they continue to stay because they do not want to lose the time invested working at the institution, particularly in regard with pay, benefits, and a pension. In other words, stress leads to unhappy workers who feel trapped into staying in a job they dislike.

Constant exposure to a working environment involving violence, negativity, and risk leads to

long-term physical and psychological symptoms. On a physical level, workers can experience headaches, irritability, muscle tension, increased heart rate, and fatigue. Long-term effects can lead to serious medical issues of high blood pressure, heart attacks, and strokes, to name a few. The psychological effects, though, many times go unnoticed or are ignored as the outcomes of stress. These include loss of trust, lower ability to concentrate, hypervigilance, cynicism, loss of empathy, detachment from others, and changes to worldview. Further psychological effects show a prevalence of substance abuse, mental health issues such as post-traumatic stress disorder, depression, and a higher risk for suicide.

The aforementioned consequences of stress affect correctional officers, but the organization suffers as well. The financial costs are great in institutions where excessive sick time or disability leave become the norm. Replacements may be difficult to find resulting in overtime and short staffing, which compounds the level of stress officers experience. Officer inattention and decreased work performance threaten the security of the institution as well as the safety of other staff and inmates. Employee turnover requires the expense of hiring and training new officers who lack the knowledge and experience working with the inmate population. These conditions make the institution ripe for inmate conflict, disturbances, and riots.

Combatting Stress on Organizational and Individual Levels

Administrators have significant influence over the work environment. Research suggests that promoting fairness through policies and procedures and giving correctional officers input into decision-making, particularly as it relates to their position, can help promote a less stressful work environment for correctional officers. Open communication, training, and professional development all enhance positive supervisory support for correctional officers. Often in correctional settings, the supervisory style reflects a paramilitary authoritative leadership, even if it negatively affects staff morale. Thus, administrators must first push toward a more transformational style of leadership that emphasizes supervisory support as a standard expectation. Management's role

should include empowering, coaching, and mentoring correctional officers by providing the guidance to overcome work pressures and problems. Budgetary decisions must focus on proper staffing, providing working equipment and maintenance of the facility, as well as funding necessary treatment programs for the reduction of inmate conflict. Administrators can also sponsor informational sessions on healthy outlets to stress through professional development and encourage employees to use break periods for mindfulness, exercise, or relaxation techniques. Finally, administrators can encourage wellness programs for the staff, employee assistance programs, and ongoing training on stress for both leadership and officers.

On an individual level, correctional officers should strive for a healthy lifestyle. Healthy eating of more protein-based foods, less processed food, and avoiding high intake of caffeine and alcohol can counter the physical effects of stress (e.g., blood pressure). Regular exercise also relieves the effects of stress by producing chemicals in the brain that not only increase energy levels but also improve alertness and concentration. Exercise can decrease tension, lower anxiety and depression, and improve sleep patterns. In addition, correctional officers can learn and engage in relaxation techniques, such as deep breathing, mindfulness exercises, yoga, or massage. Finally, correctional officers can learn to not take their work stress home so that they can enjoy their personal life.

All workers have stress, but research indicates that criminal justice, particularly corrections, personnel have higher levels of occupational stress based on exposure to danger, injury, violence, and death. The research continues to uncover the connections of the work environment to stress as well as its outcomes but, at the same time, creates the possibilities for intervention and prevention. Combatting occupational stress should be a central task for administrators. Creating a positive work environment with satisfied workers ensures better health outcomes, higher job performance, and less worker turnover. Using an evidence-based approach ultimately maximizes financial resources, creates efficiency within the institution, and increases the safety and security of both correctional staff and the inmates.

CORRECTIONAL OFFICER'S ATTITUDES TOWARD OFFENDERS

Correctional officers (COs), sometimes known as *prison guards*, are the security staff tasked with the care and custody of the prisoners who reside in prisons, jails, and correctional institutions. These prisoners include those who have been charged with a crime and are remanded to custody to await their trial and those who have been convicted of a crime and sentenced to a period of custody. COs might supervise all adult male, all adult female, or all juvenile offenders. A substantial proportion of the research on COs has been carried out on those who supervise sentenced adult male offenders, as they make up the majority of the prison population.

COs are responsible for maintaining the safety of prisoners, other COs, and facility staff; the physical correctional facility; and themselves. Frequently, COs must balance conflicting priorities,

although the principle of *security first* is widely accepted. Yet since the 1980s, expectations for COs have expanded to include supporting offenders in their successful reentry into the community by playing a role in their rehabilitation. The CO's attitude toward offenders is one factor that is likely to affect the successfulness of this goal. This entry focuses on the nature of, and influences on, CO's attitudes toward offenders.

Measuring CO's Attitudes Toward Offenders

Although there are multiple definitional theories of attitudes, a commonly accepted approach defines an attitude as an evaluative judgment based upon a summary of the information derived from cognitive, affective, and behavioral sources. Attitudes are usually measured using a survey whereby participants are presented with a small number of statements that are considered to represent the attitude of interest. Participants are asked to rate their level of agreement on a scale that ranges from *strongly agree* to *strongly disagree*. These scales are known as *Likert-type scales*. However, researchers may label identical statements as representing different attitudinal orientations. For example, the statement, "Trying to rehabilitate prisoners is a waste of time and money" could be used to measure "attitudes toward prisoners," "support for rehabilitation," or "support for punishment," depending on the researchers' theories about the attitude they are trying to measure. Consequently, CO's attitudes toward offenders come in many different shapes and sizes. Examples include (but are not limited to) attitudes/perceptions toward prisoners, attitudes toward correctional work, beliefs about the prison, interest in contact with inmates, human service/treatment service orientation, interest in counseling roles, rehabilitation orientation/support for rehabilitation, and punitiveness/punishment/control/custody orientation. The combination of CO support for rehabilitation and support for punishment is termed *correctional orientation*.

General Attitudes of COs Toward Offenders

In 1973, in a seminal article, David McLaren described the relationships between inmates (*cons*), COs (*backs*), and rehabilitation or

treatment staff (*educated screws*). In particular, McLaren described how the varying role expectations of COs and treatment staff led to conflict in attitudes toward prisoners and therefore how to treat them. Since this time, a majority of the research on COs' attitudes has also included non-custodial staff, such as program officers, social workers, institutional parole officers, psychologists, psychiatrists, and administration staff. When the attitudes of COs toward offenders have been compared to the attitudes of noncustodial correctional staff members, COs have consistently been found to hold more punitive attitudes toward offenders. As COs are increasingly expected to serve rehabilitative functions, their attitudes can lead to role conflict and confusion, which in turn leads to occupational stress. Therefore, one of the reasons for studying COs' attitudes is to determine the factors that contribute to punitive or rehabilitative attitudes toward prisoners, so that correctional agencies can hire and train COs who will best fit with the goals of their institution.

Contributions to CO's Attitudes

Two models have been proposed to explain CO's attitudes. They are the individual experiences/importation model and the work role/prisonization model. According to the individual experiences/importation model, an employee's perception of his or her correctional work is determined by the individual characteristics and experiences that he or she brings to the correctional workplace. These characteristics include gender, age, race/ethnicity, education, marital status, and political ideology. According to the work role/prisonization model, the prison environment, including the role demands of the occupation, lead to the development of certain attitudes, despite personal characteristics. Characteristics subsumed within this model include years as a CO (tenure), security level of the institution, post assignment (those with more or less inmate contact), perception of dangerousness, role stress, job variety, whether the person's work environment impacts negatively on his or her family, whether negative family environment issues are impacting on a person's work, integration, input into decision-making, organizational fairness, job satisfaction, job stress,

supervisory support, peer support, organizational commitment, and burnout.

Punitiveness/Support for Punishment of Offenders

Many of the reasons COs may hold punitive attitudes toward offenders are the same as the theoretical reasons for punishing offenders that underlie the criminal justice systems. COs may therefore hold punitive attitudes toward offenders because they believe in the legal principles of deterrence, just deserts, retribution or revenge, and incapacitation.

Just deserts is the premise upon which many sentencing decisions are based. It is the sentiment that the severity of the punishment should be proportionate to the harm caused by the crime and that the law is not served if a crime goes unpunished or is punished too lightly or too heavily.

The principle of *deterrence* is based on the premise that future crime will be prevented if potential offenders believe that if they break the law they will be punished. There are two kinds of deterrence: *specific* and *general* deterrence. Specific deterrence is conceptualized as the deterrent effect of the sanction on the specific person who perpetrated the crime, such that he or she is less likely to commit the crime in the future. General deterrence is conceptualized as the impact that the sanction of one offender for a specific crime will have on other potential offenders of that crime. The principle of deterrence is based on the theory that people carefully weigh the potential gains for committing a crime, against the potential costs. Thus, if the costs of committing a specific crime are high, such as a long period of incarceration or capital punishment, the potential criminal will be deterred from committing this offence. The principle of specific deterrence is most relevant to COs who may hold punitive attitudes toward individual offenders because they believe that if the offender's punishment is severe enough, the offender may not reoffend in the future.

The principles of *retribution* and *revenge* are closely related to just deserts. Yet, while just deserts posits that the punishment should be proportionate to the crime, revenge usually entails the punishment exceeding the harm caused by the crime. While people sometimes cite the deterrence

principle as motivating support for revenge, support for revenge is characterized by a strong emotional valence, with powerful emotions such as anger, fear, and shame being primary motivating factors. Thus, positive attitudes toward revenge are based heavily on emotional reactions.

Incapacitation involves placing a physical sanction on an offender that prevents the offender either temporarily or permanently from committing a crime in the community, although prison-based crimes are still possible. Incarceration is a form of incapacitation as the offender is physically removed from society. A lesser form of incapacitation is house arrest. The most severe form of incapacitation is the death penalty. Within correctional facilities, offenders can be further incapacitated through the use of segregation or solitary confinement. COs may support more severe forms of incapacitation if they believe the existing form of incapacitation is insufficient to serve the other principles of sentencing.

Contradictory Attitudes: Individual Offenders

COs can hold what appear to be contradictory attitudes toward offenders. While it may seem like a CO would support either rehabilitation or punishment of offenders, research has demonstrated the COs can be supportive of both. For example, COs may believe that offenders should be punished first (i.e., incapacitated) and then offered rehabilitation. CO's attitudes toward offenders also vary widely depending on the individual offender. Thus, they may harbor rehabilitative attitudes toward some offenders and punitive attitudes toward others.

The unique role of COs provides the opportunity to evaluate whether the punishment each offender is receiving meets the COs' personal standard, based on their beliefs in the just deserts, deterrence, and revenge principles. In some cases, COs consider the just deserts principle to determine whether they believe that an offender's sentence was adequate and consistent with other offenders' sentences. In other cases, they consider whether rehabilitation programs are likely to change the individual offender's future behavior. These judgments are usually based on the offender's crime and the offender's institutional behavior.

For example, offenders who are considered manipulative, or tend to be disobedient, or aggressive, typically engender more punitive attitudes. Similarly, an offender whose crime is considered more objectionable (especially sexual crimes or crimes against women or children) may elicit more punitive attitudes, especially if their sentence is considered to be too lenient. COs are also more likely to believe that rehabilitative interventions will be unsuccessful with these offenders. On the other hand, if an offender commits a nonviolent crime and is cooperative in jail, a CO is more likely to conclude that rehabilitation will be effective and therefore be supportive of this intervention. COs may also be more lenient and helpful with these offenders.

Empathy Versus Dehumanization and Deindividuation

COs may feel less punitive toward offenders based on their capacity for empathy. Empathy is an emotion that involves being able to understand and share the feelings of another person. When COs relate to the experiences of offenders, they are more likely to hold positive and rehabilitative attitudes toward them. Although some people are naturally more empathic than others, empathy is affected by how much one person is like the other person. Thus, COs are more likely to have empathy toward prisoners who are the same race, gender, or age as them.

Dehumanization is the opposite of empathy. It involves stripping a person of the positive qualities associated with being human. In prison, this may be achieved by seeing prisoners as being fundamentally different and being *monsters* or *animals*. This gives COs psychological license to treat prisoners as being less than human and wanting to punish them. Deindividuation is a related phenomenon whereby groups of individuals in positions of power over other groups lose their empathy and sense of personal responsibility for their behavior toward others of whom they are in control. Deindividuation was dramatically illustrated in Philip Zimbardo's famous Stanford Prison Experiment in which university students assigned to guard-like positions over other students in a simulated prison began to abuse their peers in a matter of days.

Knowledge

COs' knowledge of the research on human change, in particular, the effectiveness of rehabilitation on generating prosocial and law-abiding behavior in offenders, also influences their attitudes toward offenders. Specifically, while the deterrence principle is a cornerstone of the criminal justice system, whether or not criminal sanctions deter criminal behavior is an empirical question. Importantly, the outcome of a large body of research indicates that the specific deterrence principle (in particular) is without evidentiary support. Simply, harsh punishment or sanctions do not create prosocial behavior. Furthermore, research has shown that certain courses of rehabilitation are effective in reducing later reoffending rates. In this context, it has also been established that COs can play an important role in influencing a prisoner's institutional behavior and facilitate the effectiveness of institutional rehabilitation initiatives. When COs are knowledgeable about and believe in these research findings, they are more likely to hold positive attitudes toward prisoner rehabilitation. When they are not knowledgeable about or do not believe in rehabilitation, they are more likely to hold punitive attitudes toward offenders.

Stress and Burnout

COs' attitudes toward offenders can also change over time. One reason a CO's attitude may become more punitive is due to workplace stress and its consequence, burnout. Burnout is characterized by a depletion of an individual's physical and mental resources.

Burnout contains three problematic elements: depersonalization, reduced personal accomplishment, and emotional exhaustion. Similar to dehumanization and deindividuation, depersonalization occurs when job frustrations lead to more negative work-related attitudes and reduced concerns for prisoners. A reduced sense of accomplishment occurs when feelings of inadequacy, futility, and failure set in. Finally, emotional exhaustion occurs when feelings of overextension lead to decreased job productivity.

Numerous characteristics of the correctional environment and the CO's duties facilitate burnout. Factors that have been identified include

workload, understaffing and excessive overtime, shift work, supervisor demands, role conflict, confusion about the job expectations, overcrowding, lack of environmental control, lack of participation in decision-making, prisoner contact, prisoner demands and attempts at manipulation, confrontations with prisoners and threats of violence, and conflicts with coworkers.

When COs experience burnout, they become unmotivated to do the extra work that it often takes to act in alignment with their underlying attitude. Furthermore, the principle of cognitive dissonance has shown that when people's behavior does not align with their attitudes, the sense of discomfort this generates leads people to change their attitudes instead of their behavior. In this way, burnout not only drains the CO's energy, it depletes his or her pro-rehabilitative attitude. Consequently, it is in the best interest of prison officials and the rehabilitation of its prisoners to mitigate the deleterious effects of the prison environment by offering effective support and training to its COs.

CORRECTIONAL OFFICERS

There are almost 500,000 correctional officers in the United States, who are responsible for the safety and security of over 2 million prison and jail inmates. The United States has the highest rate of incarceration in the world and continues to grapple with an effective and cost-efficient means of punishing or correcting those who violate the law. Prisons and jails are overcrowded, underfunded, and understaffed. Those who work as correctional officers receive minimal training and low salaries to perform the vital role of keeping prisoners in correctional facilities and enhancing public safety. This entry explores the correctional officer professional, beginning with basic qualification standards and training requirements, and then moves to a discussion of the mental and physical challenges of working in prisons and jails.

Qualifications and Training

Correctional officers work at the local, state, and federal levels of government. Salaries are typically lower than most other entry-level criminal justice positions. Requirements for becoming a correctional officer vary by jurisdiction. Minimum qualifications usually include possession of a high-school diploma or general equivalency diploma, attainment of age 21 years, and no felony convictions. Most agencies require the applicant to be a U.S. citizen. Some jurisdictions, including the federal government, have maximum age requirements. Applicants for correctional officer jobs may be required to undergo physical and psychological testing. Applicants are also subject to random drug screenings prior to hiring and likely throughout one's career.

Once hired, correctional officers receive intense training that includes firearms use, self-defense, conflict resolution, policies and procedures, communication, physical fitness, and report writing. Upon completion of the formal training, officers typically undergo a period of on-the-job training where they work with a veteran correctional officer to learn the specific policies, processes, and programs of their post or institution. Some correctional officers are sworn peace officers with powers similar to, or the same

as, police officers employed in the same jurisdiction. Salaries for entry-level correctional officers vary, with some jurisdictions offering salaries in the range of US\$20,000–US\$25,000 and others in the US\$40,000–US\$50,000 range. The federal government and states with larger prison populations typically offer higher salaries. Correctional officers working in private prisons often earn the lowest wages.

The Federal Bureau of Prisons requires correctional officers to undergo a 3-week course within 60 days of hiring. The training is provided at the Federal Law Enforcement Training Center in Glynco, GA. Advanced training programs for correctional officers are offered from a variety of agencies, including the American Correctional Association, the National Institute of Corrections Academy, the American Jail Association, and the Management and Specialty Training Center. As of 2017, Bureau of Prisons' staffing reports indicate that over 72% of the staff are male and over 62% are White.

Women constitute over 35% of the officers in state and local adult correctional facilities and over 50% of those working in juvenile facilities. Although women and minorities have made substantial inroads into the correctional profession historically, the majority of correctional officers are still White males. It was not until major policy and legal challenges were made in the 1960s and 1970s that correctional employees became more diverse and representative of the larger population. When women did gain employment as correctional officers, they were often assigned to women's institutions or limited to noncontact roles in male institutions. This treatment of women correctional officers limited their career progression, longevity, and negatively impacted their work environment.

Stress, Safety, and Job Satisfaction

Correctional officers face significant work-related stress. Criminal justice researchers, educators, and trainers devote considerable resources to examining occupation stress among correctional officers. Correctional employees often have higher rates of divorce, substance abuse, mental health challenges, and physical injury or illness than other occupations. Additionally, higher rates of

absenteeism, turnover, and burnout are observed among those individuals who work in prisons and jails. These challenges are often the result of the organizational structure, architectural design, and long-standing correctional practices. It is well-documented that correctional officers work long hours, lack career progression opportunities, lack work and social support mechanisms, and spend their days working with convicted criminals. Further, unlike their law enforcement contemporaries, correctional officers lack the prestige, salaries, and opportunities for positive personal, community, and professional interactions.

Stress and job dissatisfaction among correctional officers can have major implications for correctional institutions. Low morale, role ambiguity, cynicism, alienation, and other stressors officers experience negatively impact recruitment and retention of personnel, as well as the safety and security of officers and inmates, and contribute to corruption and other forms of misconduct. Some research indicates a gendered nature of job stress and satisfaction, wherein female correctional officers experience stress differently than their male counterparts. Other research fails to find a relationship between officer demographics, such as gender and race.

Regardless of the officer's race or gender, stress among correctional personnel can be mitigated by institution, social, and community factors. Officer's perception of peer and supervisory support often serve to diminish work stress and elevate job satisfaction. Likewise, family and community support can impact officer's attitudes and performance by buffering the negative aspects of the prison work environment. Prisons' and jails' environmental conditions can also impact inmates and employees. Lighting, cleanliness, air quality, natural sunlight, functional equipment, noise levels, and overall workplace conditions can be managed to promote well-being for staff and inmates. Younger officers and those with higher educational levels are likely to experience higher levels of role conflict, stress, and job dissatisfaction and perceive their workplace as more dangerous.

Use of Force and Misconduct

Prison and jail settings provide an environment conducive to corruption, abuse of power, and other

forms of employee misconduct. The coercive nature of correctional facilities, the power differential between the inmates and staff, and the closed nature of traditional prison operations allowed staff and inmates to engage in coercive, inhumane, and repressive behavior throughout the history of American carceral state. For most of U.S. history, there was little concern about inmate's rights and their treatment while incarcerated. Hands-off policies were followed by state and federal courts ensuring that prison administrators maintained sole responsibility and control for inmate and guard behavior. However, over time, challenges to the iron rule of prison wardens came under more scrutiny as civil rights, including inmate rights, found their way into the narratives of reformers, activists, advocates, clinicians, scholars, and the general public. The U.S. Supreme Court finally had to recognize the injustice, abuse, and corruption in correctional facilities across the country. It was only then that real and lasting changes occurred throughout the corrections profession.

Practitioners and scholars have long studied the manner in which power and control are exercised in correctional institutions. The use of force by correctional officers is at times required to control an unruly inmate; however, some guards became too reliant on it in a prison setting where it was accepted as a necessary and consistent practice. Some officers were malicious or sadistic in the use of force, thereby threatening the safety of inmates and other officers. Further, excessive and arbitrary use of force contributed to mistrust, retaliatory violence, and institutional unrest. Abuse of authority; discrimination toward inmates; and physical, psychological, and sexual intimidation and manipulation all threaten the balance of power and control within correctional institutions. When power and control are unbalanced, the institution becomes rife for major incidents, such as escape, riots, assaults, and even death.

Correctional officers may engage in other forms of unethical, deviant, or criminal behavior. Scholars identify various types of correctional officer deviance, including deviance against the prison or jail, prisoners, and coworkers. Correctional officers have been known to abuse their authority by writing up an inmate for rule violations without cause, repeatedly conducting *random* cell or body searches, tampering with food or

personal property, denying privileges or access to institutional products or programs, and changing work or living assignments.

Deviance against coworkers is multifaceted. It can include discrimination, sexual harassment or sexual assault, boundary violations involving inmates, drug or alcohol use while on the job, bringing contraband into the facility, or engaging in inappropriate interpersonal relationships with other staff. These events can threaten the good order and discipline of the guard force, jeopardize the career of the correctional officer, and endanger the safety and security of the institution.

One of the most disconcerting inappropriate correctional officer behaviors involves sexual relations with inmates. An inmate in a U.S. correctional institution is unable to consent to sexual relations with his or her captor. As such, any type of sexual relations between officers and inmates, including relationship initiated by an inmate, are unacceptable and punishable by termination and/or criminal prosecution. The Prison Rape Elimination Act, passed in 2003, was enacted to collect and analyze data related to the sexual assault of inmates, including those acts committed by correctional staff. The Prison Rape Elimination Act also established reporting, monitoring, preventing, and eliminating standards of sexual assault and rape in prison and jails. Prison Rape Elimination Act research findings indicate that correctional staff allegedly commits more than half of all inmate sexual assaults. Further, over half of all substantiated inmate sexual victimizations are committed by female corrections officers.

Death or Injury

Correctional officers, like their police officer counterparts, face significant risk while on the job. They may experience fatal and nonfatal injuries while working with inmates. This is particularly true for male correctional officers over the age of 35. The majority of injuries to correctional officers involve sprains, strains, contusion, and abrasions. Assaults against correctional officers are most commonly committed by inmates and occur when restraining or engaging with inmates or during transport. In some cases, correctional officers are killed in the line of duty. Officer fatalities are most often the result of interactions with inmates, although some

involve self-inflicted gunshot wounds and assaults by noninmates. According to a 2011 Bureau of Labor Statistics report, correctional officers experienced work-related injuries at a rate 4 times higher than the general population and had one of the highest nonfatal injury rates of all workers. Male officers are more likely to experience a nonfatal (73%) and fatal (89%) injury than female officers.

Prison overcrowding can lead to increased stress, increased violence, and diminishing staff supervision efforts and inmate programming. As the United States continues to lead the world in the rate of incarceration of law violators, its correctional institutions are overcrowded. Further, correctional work is increasingly not a career option for high school graduates or college students. Many jurisdictions are reexamining the locations of their correctional facilities or considering privatization due to a dearth of suitable, sustainable employees. As the failure of *get tough on crime* efforts in the 1960s through early 2000s became increasingly evident, social justice visionaries, legislators, and policy makers have refined prison programs and policies to include releasing more inmates on parole, reentry programs, and improving the quality of life within the institution for staff and inmates. Although correctional officers remain at the bottom tier of the criminal justice hierarchy in terms of pay, benefits, prestige, and privilege, they face some of the most difficult working conditions.

CORRECTIONAL OFFICERS, OCCUPATIONAL DUTIES OF

Correctional officers perform a variety of duties and may work in the state or federal correctional system or work as a sheriff deputy or jail officer in the county jail system. This entry focuses on the occupational duties of the state correctional officers since custodial workers at the state level constitute the bulk of correctional employees. A brief overview of correctional officers, their rank structure, academy training, and some of the primary characteristics of correctional works are discussed. The duties of correctional officers and their underlying purposes are then described in some detail, followed by a discussion of occupational stress.

Overview

Correctional officers may be of either gender, but are predominantly male, and typically work at the

more common correctional facilities for men. Correctional *line* officers typically hold the rank of sergeant or below (Correctional Officer I and II); midlevel correctional officers (Correctional Officer III and IV) include lieutenants, captains, and possibly majors. In some state prison systems, lieutenant colonel and colonel are additions to the correctional rank structure.

In order to perform the duties of a correctional officer, a candidate must attend an academy for 5–16 weeks, depending on the state. The topics and activities in the academy curriculum reflect the custodial and human service skills that will be needed, including interpersonal communication, mediation, avoidance of inmate manipulation, basic report writing, crisis intervention, first aid, manipulation avoidance, defensive and control tactics, use of force, and firearms training. Another academy topic is coping with work-related, long-term chronic stress, attributed to the risk of violence, inmate demands and manipulations, and understaffing which officers contend with over the span of their careers.

Correctional officers are the workers who maintain stability and safety at a correctional facility and who constantly supervise and safeguard the welfare of inmates and all employees. They provide a safe living and working environment for all inmates and employees. Their concerted efforts allow the other duties of correctional officers to be performed more efficiently, such as regular scheduled head counts of inmates on their housing units. The successful completion of their duties is heavily influenced by a working environment that is at times routine and monotonous and at other times tense and unpredictable. The work setting reflects the cultures and subcultures of correctional staff. Cultures are amalgams of people interacting and upholding the goals and values of the work group. The correctional work culture espouses the values of safety and security, as well as the goals of implementing a human service approach and establishing a professional code of conduct.

Major Duties

The major work duty of correctional officers is working with inmates. It can be separated under two main categories: custodial duties and human

service duties. Custodial duties are performed for the purpose of providing order, safety, and security for those who live and work in a correctional facility or institution; custodial tasks involve supervising inmate behavior, enforcing rules, and maintaining order and safety for inmates. Human service duties are essential to protect the human rights of incarcerated individuals and to establish professional, dignified conduct for those who work and live in a correctional facility; human service tasks consist of helping, teaching coping skills, and providing services to inmates.

Dependency relationships are often formed between inmates and officers in the correctional culture. On the one hand, inmates depend on the officers for protection from violent or predatory inmates, for the allocation of goods and services, for solving their problems with institutional adjustment, and for providing information about the organization and its procedures and routines. On the other hand, correctional officers depend on inmates to expedite the smooth daily functioning in the correctional facility. Officers rely on inmates to cooperate and follow the rules, to provide information about a potential threat to their personal safety, and even to assist them in the performance of their tasks. Correctional officers are in a perpetual state of alertness and readiness for any type of inmate manipulation, disturbance, or suspicious activity.

The correctional culture is at its core *people work*, developing, nurturing, and maintaining relationships. It is interacting and engaging with a variety of people, including administrative staff, custodial and noncustodial coworkers, and inmates on an individual or a collective basis. The most essential abilities for the job of correctional officer are strong communication skill and sound judgment rather than a reliance on coercion or verbal threats to establish and express authority. A reliance on coercion may provoke a violent response on the part of an inmate; thus, coercion must be used judiciously and infrequently. Highly developed interpersonal skills and the understanding of human behavior can be used to quell conflict between a few inmates or a mass disturbance, to develop respectful relationships with inmates, and to conduct daily business in a professional manner. The actions of officers are also key to the possible rehabilitation of inmates since they

are in a position to effect the most behavioral and attitudinal changes in inmates. Correctional officers have the most contact and interaction with inmates. They relay appropriate behaviors and actions for inmates, while at the same time modeling the way to speak to officers and to one another.

Custodial Duties

In terms of specific work duties, all assignments have post orders, which are essentially detailed descriptions of the tasks that are required to be performed throughout the officers' shift. The most common assignment for an officer is the supervision of housing units. The majority of officers perform this job, which consists of observation of units for signs of disorder, unusual activity, or behavior in violation of the rules. In response to problem behavior on a housing unit, officers use their discretion as to whether to issue a disciplinary ticket or to take a different action. Regardless, all incidents must be reported to a higher authority. All inmates and their cells or units must be routinely and randomly searched for prohibited items (following the guidelines for pat downs and strip searches). Officers must also collect random urine samples for testing to detect evidence of drug usage.

Periodic patrols of housing units and work assignments are also conducted, along with counts of inmates at regular and irregular intervals. Officers are tasked with maintaining control and discipline of inmates, including the use of physical restraint and restraining devices, handcuffs, leg irons, and belly chains. The observation of inmates in all areas of the correctional facility is needed to identify suspect individual or collective actions or to detect rule violations. Incidents on housing units commonly involve personal or adjustment problems and minor disputes among inmates. It may be necessary to counsel the inmate or inmates concerning institutional rules, emotional problems, and coping strategies. Writing up an inmate or inmates for disciplinary purposes is another option. The incident must be investigated, and then, a disciplinary hearing is scheduled. Serving as a hearing officer on a disciplinary committee is another duty. Keeping a careful log of actions or incidents is required during one's shift for

historical and documentation purposes and for subsequent shift officers to read. Correctional officers may also need to supervise those inmates in segregation for administrative or punitive purposes. Some inmates may request protective incarceration for their personal safety, whereas other inmates may be sent to segregation for misbehavior or rule violation.

Another chief duty of correctional officers is to directly or indirectly supervise and monitor inmates designated to various work assignments, such as issuing clothing, towels, and sheets to other inmates. Inmates may also be assigned to institutional maintenance jobs, food service, housekeeping, janitorial and sanitation jobs, prison work industries, educational classes, and administrative duties. Officers may need to instruct their charges in the basic elements of their tasks.

Custodial duties also incorporate working for a post in the control center, such as monitoring and accessing facility gates, operating audio and visual surveillance, and responding to staff requests. Movement is also monitored throughout the facility. Additional surveillance activities include scrutinizing particular areas of the correctional facility, the yard in which the inmates are recreating, the library, classrooms, and visiting areas where visitors are admitted and their belongings searched. Custodial duties also include conducting periodic parameter patrol by foot or rover vehicle to ensure the integrity of the facility and the grounds. Officers may also serve on relief duty filling a variety of work vacancies caused by officers on sick time or taking time off.

Human Services Duties

Although most duties of correctional officers are custodial by nature, there are a number of human service tasks that are also performed. Officers must oversee and attend to the basic needs of inmates. They must obtain and deliver meal trays, bedding, towels, uniforms, and supplies as needed. In addition, correctional staff are often called upon to settle inmate disputes or to assist inmates with adjustment problems, mental health problems, or requests for cell or room changes. Moreover, officers may be placed in the position to console or advise inmates with personal problems. An example would be an officer witnessing an

agitated inmate on his unit and engaging the inmate in conversation during which the inmate confides that his son was killed during a drive-by shooting. Making sure that inmates receive the items and services they are supposed to receive is critical to institutional stability; delivering items (e.g., medication, hygiene products, mail) and ensuring services (e.g., sick call, library and recreation time) are received are primary duties. A human service approach integrated into duties is intended to reduce the stress of being incarcerated and improve the quality of life of inmates.

Specialized Duties

The variety of duties that must be completed by correctional staff is extensive. This further highlights the significant roles that these officers assume in their work as a correctional officer. There are specialized jobs that are available for correctional officers. Serving as a member of a special security team is one of these positions. A correctional emergency response team (CERT) is a highly trained, tactical team of usually eight correctional officers and two squad leaders who respond to incidents, riots, cell extractions, and major disturbances. CERT members are required to be on call and available to respond at all times.

Possible duties of CERT members may include the transportation of high-risk inmates, extraction of uncooperative inmates from their cells, daily full cell searches and high-profile security, resolution of riots or a hostage situation, and crowd control. The CERT wears extensive gear, including body armor, helmet, tactical gloves, and riot shields. A CERT officer may also be outfitted with a taser, pepper spray, or lethal weapons such as firearms.

Occupational Stress

Research shows that correctional duties are challenging and stressful. Officers report more sick leave and stress-related illnesses than other state workers. Officers also report role-conflict, trying to blend their custodial duties and a human service orientation. As mentioned, correctional officers have a variety of duties to perform throughout their shift. Although their duties are usually routine and mundane, unexpected incidents can

disrupt their work routines. In such instances, officers are required to use their discretion, to be flexible and versatile, and to utilize their interpersonal and communicative skills.

Final Thoughts

Although custodial duties are important for facility safety, human service duties are also essential. The performance of such duties allows officers to safeguard inmate rights and to help inmates cope on a daily basis. Instances of victimization and failed inmate assistance can be reduced or eliminated, and joint staff and inmate problem-solving can be facilitated with the ultimate result of a humane work and living environment.

CORRECTIONAL PROGRAM ASSESSMENT INVENTORY (CPAI)

The Correctional Program Assessment Inventory (CPAI) is a copyrighted instrument designed to be administered by certified evaluators with in-depth knowledge and training in the area of correctional treatment and program evaluation. This entry provides a brief account of the research issues that led to the CPAI's creation and a description of the

instrument and discusses the validity of the instrument and the benefits the measure brings to policy makers and clinicians in corrections to assist them in providing quality services.

Research That Led to the Creation of the CPAI

Until the late 1970s, there was considerable skepticism that psychologically based treatment programs were effective in reducing offender antisocial behavior (e.g., recidivism). This state of affairs was challenged by some psychologists working in the corrections and forensic fields who generated narrative reviews of the research literature on the effectiveness of offender treatment programs. Subsequently, this perspective was confirmed when investigators employed meta-analytic methods to identify which types of programs were the most effective and provided precise statistical estimates of the reductions in recidivism. The end result was the generation of a set of principles of effective correctional treatment. The core constituents of these principles were essentially that treatment programs were behavioral in nature. Moreover, they had to target offenders' antisocial values and behaviors that reinforced their criminal lifestyle.

In the late 1980s, it became obvious that this promising advance in what works in offender treatment had to be extended to regular, real-life/routine programs, that is, those programs conducted by government and private agency clinicians working in prison- and community-based adult and juvenile settings. This initiative resulted in the creation of the CPAI by Paul Gendreau and Donald Andrews. The instrument consisted of items derived from the research literature, the authors' personal experience as clinicians and evaluators in corrections, and the clinical wisdom acquired from other colleagues who had run successful correctional treatment programs. The CPAI was first used in a large-scale survey in 1990 to assess 100 Canadian federal prison- and community-based substance abuse programs. Since then, the CPAI has been employed in surveys of offender programs in several Canadian and U.S. jurisdictions. As a result of training sessions conducted by CPAI staff, many of the core items of the 2010 revision (CPAI-2010) have found their way into the accreditation standards of the

correctional services in the United States and Canada, as well other countries, including Australia, New Zealand, Sweden, and Wales.

Description of the Instrument

The copyrighted instrument has undergone several revisions, the latest of which was published in 2010 (and continues to be updated to include latest research in the area). This version comprises 143 items classified into 9 domains. One of the domains, program demographics (10 items), is not scored. The scorable domains (with the number of items in brackets) are as follows:

- organizational culture ($n = 9$)
- program implementation/maintenance ($n = 10$)
- management/staff characteristics ($n = 18$)
- client risk-need practices ($n = 13$)
- program characteristics ($n = 25$)
- core correctional practices ($n = 45$)
- interagency communication ($n = 5$)
- evaluation ($n = 8$)

Core correctional practices, the latest addition, are considered to be critical for determining whether treatment staff are delivering the treatment with therapeutic integrity. Within this dimension, there are eight clinical components. These are:

1. anticriminal modeling,
2. effective reinforcement,
3. effective disapproval,
4. problem-solving techniques,
5. structured learning procedures,
6. effective use of authority,
7. cognitive self-change, and
8. relationship practices.

There are three scoring categories: Very satisfactory (70%), Satisfactory (50–69%), and Unsatisfactory (< 50%). The majority of programs assessed have received unsatisfactory ratings. This is expected, according to some experts in the field who have expressed concern about the quality of real-life/routine programs and given the fact that technology transfer of the scientific literature is a

slow process since so many practitioners are not trained in clinical/forensic psychology.

Validity

Most important, the construct validity of the CPAI has been established. Two studies have addressed this question. In the first, researchers gathered 173 studies from the published offender treatment literature. Program descriptions provided by each of the studies were assessed on their quality using the CPAI. Overall, the CPAI program scores correlated well with reductions in recidivism ($r = .46$) with the client risk-need practices and program characteristics domains among the most robust predictors ($r = .41$ and $r = .43$, respectively). Next, correlations between individual scale items and recidivism outcomes were tabulated. A number of items are correlated (i.e., $r \geq .25$). Lastly, treatment programs were grouped in terms of quality (i.e., high, medium, or low) based on their CPAI scores. The mean effects with recidivism were $r = .20$, $r = .11$, and $r = .01$, respectively.

As noted, the validity of the CPAI with regard to real-life/routine programs was crucial for establishing the applied utility of the measure. The CPAI was administered to 38 in situ reviews of Ohio-based offender treatment programs, which included treatment and matched comparison groups (i.e., gender, race, actuarial risk measure score) and used reincarceration as the criterion. Even though many of the programs were ineffective (occasionally lower recidivism rates were found for the comparison group), the predictive validity of the CPAI total scores was supported. The correlation with outcome was $r = .41$ among a sample of program completers and $r = .32$ among those that did not complete the program. It was found that the program implementation/maintenance domain was a powerful predictor of recidivism ($r = .54$ and $r = .46$ for the two samples), followed by client risk-need practices and program characteristic domains (r s from .30 to .52 for each sample). A number of items from the CPAI were isolated and correlated with treatment outcome, which found correlations of $r = .60$ for all offenders and $r = .47$ among program completers.

With respect to individual items, potent correlations (i.e., $r \geq .25$) with outcome were reported

across all offenders, particularly from the domains of program implementation and maintenance, program characteristics, and client risk-need practices. Programs were categorized as high, medium, low, or very low based on their CPAI scores. Reductions in recidivism of 22%, 10%, and 5%, respectively, were obtained, with those rated as *very low* actually increasing recidivism by 19%.

Benefits

As a result of employing the CPAI over the years, users have given feedback regarding the benefits it provided their organizations. It should be emphasized that the goals of all the activities noted below are framed in a positive way. The CPAI should be used to:

1. evaluate funding proposals from prospective service providers,
2. provide credible scientific and clinical rationales for treatment,
3. identify the most frequent deficits in programs,
4. reinforce program elements that have been effective,
5. evaluate the integrity of the therapeutic process with observations of staff clinical skills,
6. evaluate external service contracts,
7. assist in providing technology transfer to management and line staff as to what works, and
8. stimulate the organization to conduct further evaluations of treatment services.

In summary, the evidence is convincing. Well-founded principles now exist with which to guide the development and administration of offender treatment programs, whether situated in prison or the community. Such programs can generate meaningful reductions in offender recidivism, resulting in sizeable cost-saving benefits. The CPAI-2010 offers practitioners a useful methodology to promote the development and growth of effective service delivery that will benefit the lives of offenders and protect the public.

CORRECTIONAL PSYCHOLOGY PRACTICE, ETHICAL ISSUES IN

Since the mid-1960s, the United States' social and political wars on crime and drugs have shifted attention away from rehabilitation to increased punishment of offenders. Consequently, among the more than 2 million individuals incarcerated today are many who are mentally ill and addicted to drugs and in need of psychological, psychiatric, and drug addiction treatment. As a result, many U.S. prisons have also become de facto mental health treatment facilities required to respond to increased demands for mental health and drug addiction treatment services.

This demand for treatment has resulted in the increased hiring of clinical and correctional psychologists, counselors, and other treatment providers. Regardless of the focus of their training background, psychologists who are employed to work in corrections agencies and facilities have become known as *correctional psychologists*, engaged in the practice of correctional psychology. However, the evolving punitive environments in

which they provide services have resulted in unique challenges to their professional codes of ethics and standards of practice, challenges that are often not easily resolved. To understand why, it is helpful to have a working definition of ethics, contributive schools of ethical thought, and their interface with the criminal justice/correction system and correctional psychology practice.

Ethics

The word *ethics* is derived from the Ancient Greek word *ethos*, meaning *custom* or *habit*, and discussions about ethics date back as far as Plato and Aristotle, if not beyond. Over time, discussions about which customs or habits are in the best interests of individuals, communities, and societies evolved into a branch of philosophy that involves systematizing, defending, and recommending individual and social concepts of right and wrong conduct. It is important to understand that philosophical ethical discourse does not directly determine what constitutes morally right or wrong conduct. Instead, such discourse attempts to provide a rationale for arriving at answers to social questions regarding what conduct or habit is morally good or evil, right or wrong, as well as what wrong behaviors constitute a crime and deserve what type of justice.

Schools of Ethical Thought

Although diverse philosophical schools of ethical thought evolved over many centuries, for the purpose of this discussion there are three enduring schools of principle-based ethics that are applicable to correctional psychology practice: *virtue ethics*, the moral character of a person (e.g., what virtues should a person have); *deontological (rule-based) ethics*, the evaluation of the moral rightness or wrongness of an act by its compliance with rules or duties associated with the act consistent with a moral norm leading to an obligation to take or not take certain actions regardless of the consequences; and *consequentialist ethics*, the evaluation of the moral rightness of an act by how much the consequences of the act contributes to the greater good (e.g., *the greatest good for the greatest number, the ends justify the means*). When applied to real-life situations, these three

schools of ethical thought fall into the philosophical category of *applied ethics*. However, it is important to understand that although each of these schools of ethical thought contributes to principled reasoning concerning what morally defines right and wrong conduct in real-life situations, the ethicality of an act is a separate consideration from the act itself. In other words, an act is ethical only because it does or does not meet related ethical principles.

These schools of ethical principles clearly interface with criminal justice and corrections because criminal justice is a legislated process that evolves from the prevailing cultural and sociopolitically defined concepts of right and wrong behavior, what constitutes right and wrong conduct, and how to best manage or *correct* wrong conduct (criminal behavior) in the interests of social order and public safety. This entry will return to these schools of ethical thought later.

Criminal Justice and Corrections

The current U.S. criminal justice system evolved over hundreds of years and is historically rooted in the notion that wrong behavior is best managed and deterred by punishing violators of the rules of social conduct and order in proportion to the seriousness of their crime. The operationalized tools to accommodate these corrective goals are provided and enforced by agencies and facilities designed to manage and contain offenders during their sentences. This process eventually coalesced into the field of corrections, generally defined as a collaboration of agencies responsible for the management of offenders sentenced through the criminal justice process. Together, the criminal justice process and corrections comprise the criminal justice system.

The Integration of Psychology and Corrections

Because the criminal justice system and correctional psychology ultimately have the same consequential goals—individuals becoming more prosocial and law-abiding citizens—one might reason that the practical integration of correctional psychology into the field of corrections would be an easy and collaborative one, but it has not been.

The core mission of criminal justice is to contribute to public safety by correcting and deterring antisocial behavior, primarily but not exclusively, by imposing varying sentences of punishment for not following social and legal rules of acceptable conduct. Therefore, the primary obligatory ethic of the criminal justice process is rule-based: Violating the law obligates punishment. The relationship is noncollaborative and adversarial: the state against the offender on behalf of the victim and public. The criminal justice system imposes punishment and is not concerned with additional harms done to the offender, the offender's family, the community from which the offender comes, society at large, or whether the results of its punitive practices (e.g., deterrence and reduced recidivism) are in fact beneficial to the greater good in the interests of public safety. And most important for the purposes of this discussion, the punitive ethic of the criminal justice system is primarily concerned neither about an offender's need for treatment nor about the ethical principles of those providing that treatment (which will be discussed momentarily).

By contrast, the profession of psychology is by definition a helping profession regardless of where it is practiced—a profession primarily concerned with helping those who need mental health services get them so that they can flourish and lead more fulfilling and productive lives. These services are provided in accordance with a specific code of ethics and standards of practice that, among other principles, avoid doing harm to others. It is to those ethical principles that this discussion now turns.

Ethical Principles of Psychology Practice in Corrections

If one collapses the essential principles of virtue, deontological, and consequential ethics described earlier, one could derive the following:

Virtue ethics—be honest, courageous, kind, compassionate, respectful, help others flourish;

Deontological ethics—follow the rules and ethics codes associated with one's profession; and

Consequentialist ethics—act in such a way that one's actions contribute to the good of the state, or to the greatest number of others.

These same enduring ethical principles are reflected in the American Psychological Association's *Ethical Principles of Psychologists and Code of Conduct*. For example, Principles A (beneficence and nonmaleficence), C (integrity), D (justice), and E (respect for people's rights and dignity) reflect virtue ethics. Principles B (fidelity and responsibility) and D (*do not condone unjust practices*) reflect deontological ethics. The Preamble and Principle B (fidelity and professional responsibilities to society and communities and manage conflicts of interest that could lead to exploitation or harm) reflect consequentialist ethics.

A similar set of ethical principles is found in the standards of the International Association for Correctional and Forensic Psychology. These ethical principles include respecting individual rights to dignity, self-determination (e.g., right to refuse treatment), and humane treatment, avoiding or minimizing emotional and physical harm, maximizing good by providing and advocating for competent mental health services and research, and recognizing and practicing social responsibility by understanding responsibilities to multiple clients and shareholders, including correctional agencies and staff, communities, and society at large. The principles found in these standards are not intended to supplant those of the American Psychological Association but to augment them.

These same general ethical principles were adopted by the General Assembly of the International Union of Psychological Science as well as by the Board of Directors of the International Association of Applied Psychology and outlined in the Universal Declaration of Ethical Principles for Psychologists. Noting that ethics is at the core of every discipline, the Declaration included the principles of respect for the dignity of persons and peoples, competence and doing no harm, integrity, and professional and scientific responsibilities to society.

As noted earlier, these ethical principles are separate from professional standards of practice. Standards of practice are ethical only to the extent they comply with the profession's ethical principles.

Ethical Challenges in Correctional Psychology

While one might reason that everyone who works in the criminal justice and corrections fields

should subscribe, even if implicitly, to the broadly defined goals of increasing public safety by correcting and/or treating criminal behavior within the ethical principles referenced earlier, correctional psychologists may encounter situations that challenge the ethical tenets of the profession. Historically, many of these challenges are not new. For example, many were identified and discussed over 30 years ago in the book *Who Is the Client: the Ethics of Psychological Intervention in the Criminal Justice System*, specifically in the chapter "Ethical Issues for Psychologists in Corrections."

Conflicting Treatment Ideologies

To be clear, there is no such status as *no treatment*. In a criminal justice era that has increasingly emphasized punishment over rehabilitation, punishment has been the overriding treatment method for correcting and deterring wrong behavior, regardless of an offender's mental status. Consequently, correctional psychologists may discover that some of the security, control, and punitive policies and practices within a correctional facility or of a corrections agency (e.g., probation and parole) may contribute to or exacerbate the mental illness or suicidal inclination of an offender the correctional psychologist is expected to treat and interfere with well-established psychological methods of treatment that are more likely to result in significant behavior change. These include extended periods of offender isolation (e.g., segregation) as punishment for misconduct, being a gang member, or mentally ill offenders being disciplined for misconduct caused by their mental illness (e.g., delusional ideation or a psychotic episode). Because it is seldom the case that the treatment needs of a mentally ill offender will prevail against the security and safety needs of a jail or prison, even if the implementation of those policies contributes to the mental illness of the offender, the correctional psychologist may find it difficult to resolve the treatment conflicts indigenous to such an environment.

Multiple Roles: Who Is the Client?

In contrast to colleagues who provide psychological services in a private practice or hospital setting, most psychologists who work in the

corrections field are involved in multiple roles with differing responsibilities to different clients (e.g., the public, the employing agency, the offender). First, they are employed by federal, state, or county governments or agencies who represent the public with a vested interest in public safety. Consequently, there is the covert, if not overt, expectation that correctional psychologists will first identify with the adversarial ideology of criminal justice system in the interests of public safety and only secondarily to their ethics and standards of practice.

Second, corrections psychologists are considered to be employees expected to work in compliance with their correctional employer's work rules and policies, even if doing so interferes with their ability to do the job for which they are hired, generates a potential challenge to their professional code of ethics, and/or interferes with treatment in the best interests of their clients. Challenges may include requests to reveal confidential information to security or administrative staff, not being provided a confidential space within which to provide essential assessment and therapeutic services, being involved in offender cell extractions, reporting potential offender misconduct to security or administration, dealing with staff abuse of an offender, treating an offender to competency in preparation for execution, and/or carrying a firearm, among others.

Third, psychologists also work as a treater of offender's mental illnesses or addictions, with a primary ethical obligation to advocate for and attend to their client's well-being and treatment needs consistent with professionally recognized community standards. However, doing so may be interpreted by corrections administrators and security staff as being overly sympathetic to the treatment needs of the offender rather than to the security and control needs of the agency that employs them.

Failure to meet the demands of these multiple roles and responsibilities to the public, employer, and client carries inherent risks not assumed by the criminal justice system. To fail to adequately protect the public from an offender via a duty to warn or comply with employer security and control demands may result in discipline or the loss of one's job. Failure to adequately treat an offender's serious mental health needs, particularly a suicidal one, may result in a client licensure complaint or civil litigation alleging deliberate indifference.

These risks assume greater prominence in the face of inadequate treatment resources.

Compromises in the Face of Inadequate Treatment Resources

For many correctional agencies and facilities, budgets may constrain the hiring of an adequate number of professional mental health staff to meet all the mental health treatment needs of offenders. Consequently, the correctional psychologist may need to make decisions about who to treat and who not to treat, or what treatment modality is the most practical, even if not the most effective. For example, there may be an emphasis on group therapy despite there being mentally ill offenders for whom group therapy is contraindicated. The psychologist may have clients whom they do not like or are not competent to treat, yet have no other resources to which they can refer such clients. These circumstances may pose ethical challenges that require special attention and difficult compromises.

While the overarching goal of promoting right conduct in the interests of public safety is ostensibly the same for criminal justice, corrections, and correctional psychology, the philosophical and ideological differences of emphasis on the means to accomplish this goal are stark and have made the integration of psychology within corrections a difficult process. As a result, the primarily punitive and adversarial ethic of criminal justice and correctional policies and practices creates an environment in which corrections administrators and staff may be philosophically indifferent, if not resistant, to the mental health treatment and rehabilitative efforts by psychologists and related treatment staff. At times, such efforts may be viewed as sympathizing with the offender against security, safety, and control policies, and ultimately the punitive *just deserts* ideology that the behavior warranted. It is from the clash of these two ideologies—the obligation to punish (harm) and the obligation to treat (help, but not harm)—that the ethical challenges for the correctional psychologist emerge.

Resolution of Ethical Challenges and Dilemmas: Due Process

Despite the various ethical principles that characterize good conduct for the correctional

psychologist, the resolution of ethical challenges and dilemmas in correctional psychology practice can be difficult. Standard 1.03 of the American Psychological Association's ethical principles states that if the demands of an organization with which psychologists are affiliated or employed are in conflict with the ethics code, the psychologists should "make known their commitment to the Ethics Code, and take reasonable steps to resolve the conflict consistent with the . . . Ethics Code" (p. 15). There is no definition of what constitutes reasonable steps or what to do if those efforts fail. It is important to understand that the ethics code and practice standards—by themselves—are aspirational and carry no specific legal weight. It is also important to understand that the criminal justice system is not obligated to attend to the ethical requirements of the correctional psychologist except as required by law.

In keeping with Standard 1.03, there is a process that embraces all of the ethical principles referenced above and that is the ethical practice of providing *due process* to one's correctional clients, whether it be the court, the administration of a correctional facility, an agency, or the offender. This practice involves being truthful about the scope of one's responsibilities to both the client and the organization prior to providing psychological, forensic, or research services to the offender client; reasonable information about the scope of available services; the confidentiality of those services; the goal of the services; and the likely outcomes. This information should be both verbal and documented in the client's records. The practice of providing due process to one's clients—whether offender or employer—can preemptively resolve potential ethical dilemmas before they occur. However, as a cautionary note, the need to adhere to ethical principles and standards of practice does not suffice to preempt employee discipline or legal action as a result of a refusal to comply with an employer's job expectation or court order. When such instances occur, consultation with the appropriate staff or agencies is of paramount importance.

Final Thoughts

The ethical practice of psychology in corrections is a challenging enterprise, fraught with ethical

challenges and risks. Nonetheless, the expectation is that correctional psychologists will subscribe to and adhere to the published ethical principles and standards of practice published by the American Psychological Association and the International Association for Correctional and Forensic Psychology and, when ethical challenges and conflicts occur, will explore avenues of resolution for guidance. To do less is to fall short of the expectation that psychologists will provide services in keeping with the highest ethical ideals and standards of practice of the profession in order to contribute to a safe and stable society.

CORRECTIONAL REHABILITATION PROGRAMS, EVALUATION OF

A body of knowledge has been accumulating on correctional rehabilitation programs and offender populations. This has been generated by evaluation studies that have examined the effectiveness of various types of treatment approaches in

reducing offender recidivism. Many reviews of the offender rehabilitation literature have found that while some programs have been effective in reducing recidivism, there are some programs for offenders that are not effective. This disparity in program success has led researchers to try to determine the characteristics that differentiate effective programs from ineffective ones. Programs that are poorly conceptualized, poorly implemented by unqualified staff, or target inappropriate or unalterable factors for change have little chance of reducing recidivism. Relatively little attention has been devoted to questions of what works best, for whom, under what circumstances, and why. This entry focuses on what has been learned from the offender rehabilitation literature on program evaluations.

Program Evaluations

Program evaluations are the systematic gathering and analysis of information to determine the quality and effectiveness of programs and to identify areas requiring improvement. They provide stakeholders and funders with key information and allow informed decisions to be made about the future of the program.

Stronger conclusions can be drawn about the quality and effectiveness of a correctional treatment program when a rigorous evaluation is conducted. These evaluations can involve both quantitative and qualitative methods of research. Ideally, the evaluation should be planned prior to treatment program delivery. This type of planning allows for the development of the selection criteria for participants, the assignment of offenders to groups, and the identification of appropriate measures to assess participants. Retrospective or after-the-fact evaluations are typically considered methodologically weaker and are not as highly regarded. A definitive statement about the effects of specific offender treatment programs cannot be formulated without the inclusion of a control or comparison group that was not provided with the program. Ideally offenders should be randomly assigned to *treatment* and *control* groups in order to protect against any potential source of bias in group allocation. If random assignment is not possible, a quasi-experimental design should be employed to provide a standard against which to

assess treatment effects. In a quasi-experiment, the treatment and control groups are matched on characteristics that are potentially related to outcome (e.g., age of offender, criminal history). Detailed descriptions of the characteristics of the comparison groups should also be provided.

Criminal justice officials and other stakeholders such as politicians and the general public are principally interested in recidivism as an outcome measure in program evaluation. When possible, multiple indicators of recidivism should be employed. For instance, arrests, convictions, incarceration rates, type and severity of offences, and technical violations could be examined. Furthermore, recidivism outcomes should be tracked for a suitable length of time to determine the effects of the program (e.g., 3 years).

Intermediate or before-and-after measures should also be incorporated into the evaluation design. For example, measures of antisocial attitudes, personality, or cognitive skills (e.g., social problem-solving) could be included. Others may include changes in substance use severity, educational achievements such as finishing high school, and employment achievements. Therefore, it is important that program officials include reliable and valid measures to assess these intermediate targets.

However, intermediate measures and outcome measures do not provide a complete picture of what transpired during the program. They do not reveal why a program works or does not work. Evaluations need to get inside the *black box* of an intervention program. This would provide information on what these programs do and how they do it. Evaluations can provide an assessment of the theoretical model underlying the treatment program approach and its conceptualization. Moreover, they also measure implementation and integrity. Program implementation must be carefully monitored to ensure that the program is delivered in a manner consistent with the original protocol: How many sessions were actually delivered? How long are the sessions and over which period of time? How many sessions did program participants attend?

Reviews of Offender Rehabilitation Evaluations

A large number of offender rehabilitation evaluation studies now exist that can help

inform correctional decision-making. Quantitative research synthesis techniques, also known as *meta-analysis*, have been used to analyze this large evaluation literature. Meta-analysis involves the statistical analysis of the results of a group of prior research studies. It generates a statistic called an *effect size* for each evaluation study. The effect size for an evaluation study represents the magnitude of difference in recidivism between the group that received the rehabilitation program and the group that did not receive the rehabilitation program. Meta-analytic reviews of hundreds of outcome evaluation studies have led researchers to identify a set of principles of effective correctional rehabilitation. These principles have helped to distinguish programs that reduce recidivism from programs that do not. Programs that adhere to these principles are more likely to be successful at reducing recidivism than programs that do not follow these practices.

Principles of Effective Correctional Rehabilitation

Who to Treat?

Meta-analyses have demonstrated that medium- to high-risk offenders will benefit the most from offender rehabilitation programs in reducing their reoffending. This is also known as the *risk principle*. Risk refers to the offender's probability of continuing his or her criminal behavior. These offenders will benefit more from intensive services compared to low-risk offenders. High-risk offenders are capable of change and have more to change about them compared to low-risk offenders. Research has found that low-risk offenders require minimal levels of rehabilitation services or no services at all. Generally speaking, low-risk offenders are unlikely to recidivate.

Offender Rehabilitation Targets

Reviews have demonstrated that offender rehabilitation programs should target the known predictors of crime and recidivism for change such as antisocial attitudes and substance abuse. This is also referred to as the *need principle*. Noncrime-producing factors such as self-esteem in males, anxiety, physical conditioning, and understanding one's culture or history will not have much effect

on recidivism. The results of meta-analyses have also revealed that the predictors most closely associated with recidivism are dynamic and can be changed. Other predictors that place offenders at risk of crime and recidivism such as an offender's criminal history, age, and gender are static factors and cannot be changed. As a result, static factors are not suitable targets for offender rehabilitation programs.

Behavioral Programs

Another principle that has been identified requires that offenders receive rehabilitation programs that are capable of changing the known predictors of crime and recidivism. To the extent possible, efforts should be made to match the way a treatment service is delivered and the learning styles of the offender. This is also referred to as the *responsivity principle*. In general, offender rehabilitation programs based on behavioral strategies (social learning and cognitive behavioral) are more effective than programs that are not based on these strategies. Offenders generally respond well to behavioral strategies. These strategies provide learning and skill-building experiences designed to change specific problem behaviors through such techniques as practice, role-playing, modeling, feedback, and reinforcement. The problem behaviors may include antisocial attitudes and values, antisocial peers, and substance abuse. This approach may also include techniques that would foster the development of the offender's thinking and reasoning skills, the offender's social comprehension, and the offender's social problem-solving. Interventions based on these approaches are typically very structured. Other treatment modalities that are nonbehavioral are associated with smaller reductions in recidivism. These include drug and alcohol education, talk therapy, shaming offenders, and self-help. Meta-analyses have also found that punishment-oriented programs such as *Scared Straight* and character-building programs such as boot camps and wilderness programs do not work.

Furthermore, offender rehabilitation will be more effective if the program takes into account other considerations such as the characteristics of program participants. Offenders may respond differently to program deliverers, the actual program,

and the setting in which the rehabilitation program is delivered. The considerations or factors that may impact service delivery are the offenders' lack of motivation to participate in the program, their feelings of anxiety or depression, cognitive ability, and personality. Demographic characteristics such as age, gender, race, and ethnicity are also considerations that need to be taken into account.

Multimodal Programs

Many reviews have also found that multimodal offender rehabilitation programs are more effective when programs use more than one treatment technique and focus on more than one problem behavior in the delivery of the program. Offenders typically enter rehabilitation programs with a number of problems. Multimodal programs offer a variety of interventions to treat offenders and are able to address a range of crime-producing factors at the same time. The targeted behaviors are those that are predictive of future criminal behavior and are dynamic in nature (e.g., antisocial attitudes, substance abuse).

Treatment Setting

Whenever possible, the treatment should be delivered in the community in the offender's natural environment. This may involve offenders who are serving a sentence of probation in the community or offenders who were released from prison and are under parole supervision. Community-based treatment generally produces greater reductions in recidivism than institutional or residential programs. Institutional or residential programs can be effective, but it is more difficult to achieve the same reductions in recidivism. These settings pose a number of challenges such as balancing the need for offender rehabilitation and the need for institutional security. For example, in some instances, rehabilitation sessions may need to be canceled because of custody concerns in the particular institution. In order for rehabilitation to be effective in institutional or residential settings, it may be necessary to house participants separately from the general population of offenders. This would help avoid the antisocial prison subculture and would provide a supportive context that would, it is hoped, be more compatible with program objectives.

Aftercare or Program Follow-Up

Reviews also indicate that offender rehabilitation programs should follow offenders after they have completed the formal phase of the rehabilitation program. This would provide an opportunity to administer a structured relapse prevention component or some form of aftercare. Relapse prevention assists offenders in identifying their own specific high-risk situations that may lead to reoffending. This training also assists the offender in developing appropriate responses to these situations in order to prevent relapses. Continuity of care helps maintain any positive changes gained from rehabilitation and prevent further antisocial behavior. Relapse prevention and aftercare is especially relevant for offenders with histories of problems such as sex offences and substance abuse.

Program Quality

One other factor that has been found to be associated with the effectiveness of offender rehabilitation programs is the quality of the implementation. Programs will be more effective if they are well-implemented and maintain integrity to the treatment model. Program integrity or fidelity simply refers to the extent to which the treatment is delivered as intended or planned. Problems may arise when program deliverers incorporate their own preferred treatment techniques versus those called for by the rehabilitation program. Second, program providers who are poorly trained and supervised, or unmotivated, may not deliver the optimal version of the particular program. Efforts should also be made to properly monitor or supervise program providers on an ongoing basis to ensure that they are following the program model and that there is no drift from it. Another aspect of implementation is dosage. This refers to the amount of treatment services provided to offenders. The impact of an effective treatment may be diminished if the intensity and duration of rehabilitation services is not sufficient for the particular offender subgroup receiving services. Generally speaking, more intensive rehabilitation services should be devoted to high-risk offenders compared to low-risk offenders. Successful rehabilitation programs may not be replicated in other sites because of poor implementation.

CORRECTIONAL REHABILITATION SERVICES, BEST PRACTICES FOR

Since the 1980s, considerable attention has been directed toward identifying which types of correctional rehabilitation services should form the basis of offender treatment. It has been well-established in the corrections literature that certain programs and interventions are more effective and successful than others. A program or intervention's success is reflected in its ability to modify offenders' behavioral patterns and, by extension, reduce recidivism (i.e., commit a new offense after program participation). Programs that consistently show successful efforts in rehabilitating offenders and have credible documentation of their effectiveness are highly accepted into

practice. Best practices for correctional rehabilitation services encompass successful, goal-oriented correctional initiatives that receive support by the correctional community and are recognized as being helpful to organizations and agencies. In addition to these components, best practices have a strong theoretical grounding, which help to emphasize their evidence-based approaches. These practices have evolved from years of transferring knowledge from research to correctional practitioners. This entry reviews the concept of rehabilitation and identifies the characteristics that define the best practices for correctional rehabilitation services.

The Concept of Rehabilitation

The rehabilitation ideal encompasses the broad view that offenders are unique and engage in behaviors differently based on environmental factors, psychological development, and biological influences. In other words, proponents of rehabilitation believe that internal factors or an individual's social environment causes or influences engagement in crime. The concept of rehabilitation differs from other goals of punishment in the criminal justice system (e.g., deterrence, incapacitation) by seeking to change offenders' behavioral patterns and focusing on improving offenders' lives.

Correctional rehabilitation services embody this ideology and strategically plan interventions to modify offenders' behavioral patterns. That is, rehabilitation programs and interventions do not occur by chance but are designed to include specific features. The main goal of these types of services is to reduce the probability that offenders will reoffend. In order to reach this desired goal, rehabilitation services target specific factors known to cause the offender's criminality. Not only is this aspect of services important for improving offenders' lives, but it also is a critical component to enhancing public safety. These components form the basis for the best practices for correctional rehabilitation services.

Despite the knowledge accumulation on what components correctional rehabilitation services should incorporate, research often indicates considerable heterogeneity in the effectiveness of rehabilitation programs and interventions. Studies related to correctional rehabilitation

programs and interventions find that some are effective, some are moderately effective, and some have iatrogenic (i.e., adverse effects on offenders and increase reoffending) or no effects on changing offenders' behaviors. The systematic variation in correctional intervention and program success has led to a search for the characteristics that distinguish effective treatment practices from those that are ineffective. Through the review and analysis of hundreds of studies, researchers have enhanced knowledge on *what works* in offender rehabilitation and have identified a set of principles that should guide correctional programs.

The Principles of Effective Intervention

The principles of effective intervention form the conceptual and empirical underpinnings for understanding the body of literature on offender rehabilitation. The best practices or *what works* for offender rehabilitation is not reflected in a single program or intervention but based on a body of knowledge developed over 30 years that has been conducted by numerous scholars. The *what works* movement demonstrates empirically that theoretically sound, well-designed programs that appropriately apply the principles of effective intervention can significantly reduce recidivism rates. The principles of effective intervention have three core elements—risk, need, and responsivity—that, together, form the Risk-Need-Responsivity (RNR) model. Since its development in 1990, this model has been expanded to include more principles with the intention of enhancing the design and implementation of effective correctional interventions. This section provides an overview of the RNR model.

Core Principles and Key Clinical Issues

In order for rehabilitation to be optimally effective, three conditions must be satisfied: Treatment programs should (1) deliver services to higher risk offenders (the *risk* principle), (2) target factors related to offending (the *need* principle), and (3) employ cognitive-behavioral and behavioral treatment programs (e.g., social learning, cognitive interventions), while considering offender characteristics when making decisions about the mode

and style of service delivery (the *responsivity* principle). These three conditions form the foundation of the RNR model of correctional assessment and rehabilitative programming.

The first core element of the RNR model—the risk principle—provides a guideline for *who* treatment programs should target for services. There are two aspects of this principle: (1) risk (i.e., the probability that an offender will recidivate) can be predicted and (2) treatment services (or intensity/dosage) should match offenders' risk level. Higher risk offenders should receive the most intensive services while minimal or no intervention is sufficient for lower risk offenders. The second core element is referred to as the *need principle* and advises correctional rehabilitation services on *what* to target in order to have the greatest effects in reducing recidivism. This principle posits that correctional treatment services should target the known predictors (or risk factors) of crime and recidivism for change. There are two types of predictors for crime: (1) static (i.e., unchangeable risk factors like criminal history) and (2) dynamic (i.e., amenable risk factors like antisocial attitudes). Dynamic predictors are also referred to as *criminogenic needs* and are highly correlated with criminal behavior. Thus, these factors are considered to be the most appropriate targets for correctional rehabilitation services.

The last core component is the responsivity principle, which suggests *how* programs should go about targeting offenders' needs to match the treatment services to offenders' learning styles and capabilities. There are two elements of this principle: general and specific responsivity. The general responsivity principle states that the most effective interventions tend to be those that are behavioral in nature and based on cognitive, behavioral, and social learning theories. Cognitive-behavioral treatments are short-term, goal-oriented interventions provided by clinicians, which focus on identifying, understanding, and changing criminogenic thinking patterns that sustain criminal behavior. Some examples of such interventions include Relapse Prevention, Thinking for a Change, and Aggression Replacement Training. Specific responsivity underscores the importance of considering key offender characteristics when matching offenders to treatments and staff. In order to optimize effectiveness, correctional

programs should adapt the style and mode of service according to factors (e.g., personality traits, cognitive deficiencies, anxiety) that could impede the delivery of services or offender participation in a program.

The RNR model also includes several other principles referencing key clinical issues to enhance service delivery. First, it is suggested that correctional programs employ multimodal techniques or expand their breadth of needs targeted. The effectiveness of interventions is often contingent upon the number of criminogenic needs targeted: Services are more successful when they target a higher number of criminogenic needs relative to noncriminogenic need areas (e.g., anxiety, motivation). Programs that limit the focus to one or two of these needs are unlikely to have much of an effect on offenders' overall behavioral patterns.

Second, criminogenic needs (and risk to reoffend) can be assessed by correctional staff using a *structured* risk and needs assessment instrument. Best practices in correctional rehabilitation services often use instruments that have adequate predictive validities of an offender's risk to reoffend, examine a wide range of criminogenic risk factors, and identify responsivity issues that contribute to program engagement. Some examples of assessments that are used in the field include the Level of Service Inventory-Revised, the Psychopathy Checklist-Revised, and the Level of Youth Service/Case Management Inventory. These tools assist practitioners with developing individualized treatment plans and services to target offenders' higher scored need areas. A number of studies have also revealed that these tools are useful for facilitating case management decisions and guiding contact sessions. Correctional staff have the option to use professional discretion on these tools to override the structured decision-making, but this occurs on rare occasions and must be documented to provide explanations.

Overarching Principles

The principles included in this part of the RNR model codify a theme for showing respect to the individual under treatment and incorporating ethical and humane application of empirically driven services. Best practices deliver services with respect for the person (e.g., personal autonomy,

just, legal) and the normative context. These norms may vary, however, with particular agencies based on the population they serve and the setting in which services are delivered. Another aspect of the overarching principles is that correctional programming should be based on empirically solid (i.e., validated) psychological theories of human behavior. In order to uphold this theme of respect for individuals, the RNR model of crime prevention extends to all agencies within and outside the justice system that encounter and deal with an offender clientele. These dimensions are considered *overarching* because they apply to any intervention or program, regardless of the type of treatment.

Organizational Principles

This section of the RNR model encompasses three principles that underscore the importance of appropriate staffing techniques and managerial support to maintain the integrity of such programming. It is suggested that correctional treatment services are most effective when they are offered in a community-based setting. These programs still produce meaningful reductions in recidivism, however, when facilitated in residential and institutional settings. The effectiveness of treatment services is strengthened by certain staff characteristics and practices (i.e., high-quality relationship skills, high-quality structuring skills) better known as *core correctional practices* (CCPs). The dimensions of CCPs include *effective use of authority*, *prosocial modeling* (i.e., provide directives/consequences to teach appropriate behaviors), *effective reinforcement and disapproval*, *skill development* (e.g., cognitive restructuring, problem solving), and *advocacy/brokerage*. Each of the dimensions represents best practices of interacting with offenders to enhance the quality of treatment services, which are derived from empirically validated theories of human behavior.

Finally, in order to maintain fidelity to RNR programming, it is important that staff have support from their own organization and other agencies that work directly with their organization. Within this context, managerial techniques involve the selection, training, and supervision of staff that fall in line with RNR approaches. Quality assurance becomes an important component to

building a system supportive of best practices and to enhance continuity of care.

Validation of the Principles

Given the scope of research on offender rehabilitation services, there is now sufficient evidence to enable correctional policy makers to determine meaningful inferences regarding what works to reduce recidivism. The previous compilations of research findings and recommendations provide a coherent framework of guiding principles—the principles of effective intervention. Although the research does not provide support for each of the core principles with equal volume and quality, the conclusions of systematic reviews yield remarkable consistency in their findings. The convergence in findings is noteworthy given the variation in the methodologies and analytic techniques employed in studies.

In general, the average effect of rehabilitation on recidivism is positive and relatively large. This means that rehabilitation programs and interventions are not only capable of reducing recidivism but also likely to produce large reductions in reoffending. However, rehabilitation services that achieve the greatest reductions in recidivism adhere to the RNR model. Researchers have demonstrated how the magnitude of the relationship between rehabilitation and recidivism increases as programs adhere to more of the principles. Additionally, these studies also suggest that nonadherence to the RNR model shows no effect on recidivism and may increase subsequent criminal conduct. This finding holds true across offender's sex, age, and correctional setting. Overall, the research indicates that programs that adhere to the principles of effective intervention can reduce recidivism as much as 30%.

While the literature provides a structured guideline for how programs and interventions should deliver services, it does not ensure *how well* these services will be implemented. Studies have demonstrated that evidence-based programs can increase criminal involvement if not competently delivered as intended and assessed through quality assurance processes. Thus, researchers have developed an instrument, the Correctional Program Assessment Inventory (CPAI), that evaluates programs' adherence to the principles of effective intervention and examines the quality of service.

Program Evaluation

An often overlooked component of best practices in correctional rehabilitation services is program or therapeutic integrity. Program integrity has recently gained more attention in corrections, as it is critical to ensure that offenders receive quality services capable of reducing recidivism. A high degree of therapeutic integrity means that staff are adequately trained and supervised and are able to be assessed for interpersonal skills that have been found to contribute to the delivery of effective services (e.g., CCPs). The CPAI is an assessment instrument that offers guidance on how to implement an effective program in a correctional setting.

Since its development, CPAI has undergone several revisions. As of 2018, the most current version of the instrument is called the *CPAI-2000* and includes 131 items or measures of therapeutic integrity. The instrument is subdivided into two general areas—capacity (i.e., program capability to deliver interventions and services for offenders) and content (i.e., assessment procedures and the degree to which the program adheres to the RNR model)—and consists of eight domains: (1) organizational culture, (2) program implementation and maintenance, (3) management/staff characteristics, (4) client risk-need practices, (5) program characteristics, (6) dimensions of CCPs, (7) inter-agency communication, and (8) evaluation. The goal of the instrument is to begin holding programs accountable for the types of interventions they provide and enhance the amount of effective interventions in the field.

Several hundreds of correctional programs have been evaluated using the CPAI instrument to date and, accordingly, several conclusions can be drawn. First, the vast majority of programs do not receive a passing grade and have been found to need improvement. For example, earlier studies examining CPAI scores of programs found that only a small percentage (10–12%) received a passing score. Additionally, the literature underscores the relationship between CPAI scores and treatment effectiveness. More specifically, the overall CPAI program scores have been found to strongly relate to reductions in recidivism. In other words, those programs with higher quality ratings are associated with lower recidivism rates. Further, the two studies that have been conducted to

examine the CPAI predictive validity found that *client assessment* and *program characteristics* were strongly correlated with treatment effectiveness. Additionally, one of these studies also identified *program implementation* as a significant predictor of treatment effectiveness.

These findings provide further validation of the principles of effective intervention, demonstrating that programs providing services to higher risk offenders, targeting criminogenic needs, and employing cognitive-behavioral techniques are some of the most influential approaches to offender behavioral modification. In addition to these conclusions, the CPAI evaluation results highlight an important element that contributes to program effectiveness—program implementation. Indeed, some scholars suggest that the quality of implementation might be equally as important as the type of service delivered.

Program Implementation

It is clear from the literature that effective practices for offender rehabilitation need to follow the principles of effective intervention. While these principles form the foundation of the programs, there are other characteristics associated with the most successful practices for correctional rehabilitation services. Specifically, these characteristics encompass the necessary components that help bridge empirical research with the proper implementation of programs. The transmission of empirical evidence from the producers to consumers has been identified as a major reason many programs fail or have no effect on modifying offenders' behaviors. The implementation of practices for offender rehabilitation can often suffer from organization resistance, budget costs, staff turnover, and minimal staff training, to name a few. Improper program implementation spurred in part by a lack of understanding related to how practitioners can be adequately equipped to implement correctional rehabilitation services continues to be an ongoing problem in offender rehabilitation.

Practitioners should receive adequate training (and continual training) to learn new skills and gain insight into the purpose of the intervention or program. Within this context, the goals of programs need to be discrete, clearly articulated, and easily understood by practitioners. It is

unlikely that practitioners will utilize the new information if it is not (a) easy to understand and deliver and (b) easy to incorporate into their daily practices. Thus, there should be personal communication and interaction between program designers and users to ensure proper program implementation. Additionally, supervising treatment delivery and providing feedback to users can serve as an important learning experience, enhance motivation, and ensure fidelity to the model. The most effective types of programs identified in research have been those that involve the researchers in program development, training, and observation of staff.

According to the research, effective programming is most likely when all criminal justice agents involved in the program are informed of policy changes. Further, policy changes should be a collaborative process between line-staff, managers, and program developers as staff buy in to the practice is an important component. Another way to increase the likelihood of staff adopting the correctional initiative is for managers or leaders of an organization to provide rewards or incentives to do so. Practitioners, too, should be exposed to new policy changes and provided with explanations about the importance of the correctional initiative.

While not *all* of the characteristics that define successful implementation of programming are provided here, these represent a basis for the general requirements necessary to further increase proper and consistent implementation of rehabilitation services.

CORRECTIONAL REHABILITATION SERVICES, INTENSITY OF

A fundamental understanding within the scope of correctional rehabilitation services is that correctional interventions and programs can effectively reduce the probability of an offender engaging in subsequent criminal behavior (i.e., recidivism). However, it is also understood that the effects of correctional treatment programs are heterogeneous; not all programs are equally effective, and some programs work better than others. The most effective correctional programs seem to be based on several essential principles of effective intervention, especially the risk principle, which is the most empirically validated. This principle, part of the

Risk-Need-Responsivity model of correctional intervention, explains that correctional rehabilitation services are most effective when the intensity, or amount, of treatment matches an offender's level of risk. Specifically, high-risk offenders should be exposed to the most intensive treatment while low-risk offenders should receive minimal to no treatment. Yet the relationship between the intensity of services and risk for recidivism is often not this straightforward. This entry provides a brief overview of the ways intensity of correctional rehabilitation services is tied to the risk principle, noting the suggested intensity, or dosage, for each risk level.

Risk and Intensity of Rehabilitation Services

According to the risk principle, programs should target offenders with the highest probability of recidivism and provide these higher risk offenders with the most intensive treatment for criminogenic needs. Furthermore, intensive treatment should not be delivered to lower risk offenders as it will likely lead to iatrogenic outcomes (i.e., increased recidivism). This is because interventions tend to disrupt a low-risk offender's prosocial ties and connections while increasing his or her exposure to higher risk offenders. Thus, for correctional rehabilitation services to be most effective, the intensity of intervention and treatment should be matched with offender's risk level. In other words, along with suggesting *who* should be targeted with treatment, the risk principle also suggests *how much* treatment offenders should receive by their assigned risk level.

The relationship between the intensity of correctional services—how much treatment an offender receives—and recidivism is nonlinear and moderated by risk. Understanding risk as a moderator means that the effect in the relationship between the intensity of a correctional program and its outcome (i.e., recidivism) is highly affected by the risk of the offender receiving the treatment. Additionally, treatment intensity and the outcomes of recidivism do not produce a consistent linear relationship. While the general belief is that the more an offender is exposed to rehabilitation services, the less likely he or she will be to reoffend, some suggest that the effect of treatment may diminish if an offender is exposed to too much treatment (i.e., a curvilinear relationship). Thus,

for rehabilitation services to have the best outcomes, they need to be implemented at an intensity that is just right for the offender based on the offender's level of risk.

Since likelihood of recidivism is linked to the risk level of an offender for recidivism and the intensity of the treatment he or she receives, it is important to understand specifically how these two characteristics of the risk principle interact with one another. As mentioned earlier, when it comes to low-risk offenders, it is often found that as programs become more intensive, the rate of offender recidivism often increases. Thus, for low-risk offenders, the relationship between program intensity and recidivism is found to be positive. Here, a positive relationship explains that increased treatment intensity increases the likelihood of recidivism for low-risk offenders.

For low-moderate- and moderate-risk offenders, the relationship between program intensity and recidivism mimics a U-shape. At first, there is a negative relationship between program intensity and recidivism (i.e., intensity increases and recidivism decreases). Then, at a point, there is a change in the relationship where it becomes positive (i.e., intensity increases and recidivism increases). This curvilinear relationship suggests that for low-moderate- and moderate-risk offenders too much treatment can be detrimental. Furthermore, a handful of studies have tried to quantify the number of hours of treatment that are most effective for each offender's risk level. These studies indicate that the diminishing effect of treatment intensity for low-moderate- and moderate-risk offenders begins at around 150 hr of treatment. For moderate-high- and high-risk offenders, program intensity and recidivism for moderate-high- and high-risk offenders have been found to have a relationship that is consistently negative. Although the strength of the relationship has been found to start weak, then become strong, and then plateau toward the end, research suggests that 100 hr of treatment will have little effect on reducing recidivism; however, the relationship is strengthened and has a larger effect when offenders are exposed to 200 hr of treatment with a plateau when treatment surpasses 300 hr.

The research shows that correctional interventions and treatment lead to the greatest reductions in offender recidivism when the risk principle not

only identifies who should be targeted but also provides a recommendation for how much treatment offenders should receive. Therefore, the intensity of correctional rehabilitation services should be tied to the offender's identified level of risk. Accordingly, for rehabilitation services to have the best recidivism reductions, they need to implement programming at an intensity that is not too short or not too long.

CORRECTIONAL SERVICE CANADA

Correctional Service Canada (CSC), also referred to as the *Correctional Service of Canada*, is an agency of Public Safety Canada, headquartered in

Ottawa. CSC operates under the Corrections and Conditional Release Act and is responsible for the *safe secure and human control* of men and women sentenced to 2 or more years in prison or remanded to custody. In total, then, CSC is responsible for approximately 23,000 individuals, of whom 15,000 are in custody and 8,000 are under supervision within the community.

Although it is the CSC that generally garners most of the media attention, the majority (96%) of prisoners in Canada fall under the jurisdiction of provincial or territorial correctional authorities. Individuals sentenced to fewer than 2 years or remanded into custody are housed in provincial or territorial correctional facilities governed by the corresponding province's or territory's ministry of justice or public safety. Several provinces and territories (i.e., Newfoundland and Labrador, Prince Edward Island, Yukon, Nunavut and the Northwest Territories) lack federal prisons. In these jurisdictions, then, certain federally sentenced prisoners are allowed to serve their sentences within the local penal facilities. Often, such allowances are made so that a prisoner can remain closer to his or her family, home community, and culture.

This entry begins by reviewing the operational structure of the CSC. Next, it discusses programming and services for both prisoners and releases. Last, this entry examines the challenges facing CSC.

Operational Structure

There are five CSC regions—Atlantic, Quebec, Ontario, Prairie, and Pacific, and approximately 18,000 employees manage and supervise those persons under federal custody. There are a total of 43 minimum-, medium-, and maximum-security correctional institutions, including 6 for women and 4 used as Indigenous healing lodges. CSC also operates 92 parole offices, 15 community correctional centers, psychiatric or forensic hospitals or treatment centers, reception and assessment centers, health-care centers, palliative care units, and an addiction research center. Persons on conditional release (e.g., parole, statutory release, permitted temporary leaves) are supervised by community correctional staff in community residential facilities, halfway houses, day reporting centers, and other reentry facilities operated in

partnership with such not-for-profit organizations as the John Howard Society, St. Leonard's Society, and the Elizabeth Fry Society. It costs over \$115,000 (CDN) per year to maintain an offender in a CSC institution and almost \$35,000 (CDN) per year to supervise an individual in the community. In 2014–2015, CSC expenditures totaled approximately \$2.6 billion (CDN).

Approximately 90% of federal prisoners have treatment needs, including those tied to mental illness and substance abuse, while about 70% are incarcerated for a violent crime. Of those incarcerated, most are single and comparatively less educated than citizens not involved in the justice system. Moreover, Indigenous people constitute approximately 4% of the Canadian adult population but represent 25% of the custodial population. In the Prairie region of CSC, almost half of the prisoners are Indigenous. Here, Indigenous prisoners are more likely than non-Indigenous prisoners to be sent to a maximum-level security facility. In 2015–2016, a greater proportion of Indigenous men and women prisoners than other racial/ethnic groups were serving a sentence for a violent offense. In comparison, Black Canadians comprised 3% of the general population yet represented 10% of the federal prisoner population—a 70% increase from rates one decade prior—making them the fastest growing group in federal prisons.

Programming and Services

CSC offers a variety of institutional and community-based programs and services, including violence prevention programs, family violence prevention, programs for sex offenders, substance abuse programs, and, for Indigenous offenders, programs based on traditional cultural and spiritual practices. To decrease the spread of infectious diseases, CSC also provides prisoners with condoms, lubricants, dental dams, and bleach kits for needles (though it does not supply needles). Federal prisoners who qualify also have access to overnight family visits at a unit on the grounds of the correctional institution.

The Canadian-created, empirically validated Risk-Need-Responsivity model provides the framework for many institutional and community-based programs. The *risk principle*

holds that correctional interventions have a greater chance of success when they are matched with the offender's level of risk. The *need principle* holds that correctional interventions should target criminogenic needs (i.e., dynamic risk factors), such as substance abuse, peer relations, and procriminal attitudes. The *responsivity principle* holds that correctional interventions be matched to individual learning styles and abilities, with particular emphasis on cognitive-behavioral interventions.

Supervision in the Community

All federal prisoners are conditionally released into the community under the supervision of CSC. Some are paroled after serving one third of their sentence; others are assigned statutory release after serving two thirds of their sentence. Prior to release, assessments determine the offender's need and risk levels, of which the results determine the appropriate level and intensity of community supervision, ranging from requiring periodic phone calls to the releasee's residence, the requirement that the releasee reside in a community-based residential facility with 24-hr monitoring, to frequent face-to-face meetings with the parole officer.

Challenges for CSC

CSC faces a number of challenges in fulfilling its mandate. These include an increase in the number of older prisoners, an increase in the numbers of prisoners with mental health and health-care needs, prison overcrowding, gangs, and meeting the needs of women and Indigenous prisoners. The rates of infectious disease, including HIV/AIDS, tuberculosis, and hepatitis B and C are high. Finally, it can be particularly challenging for CSC personnel to provide adequate supervision to releasees with mental health needs, sex offenders, and those residing in small northern and remote communities where there is a lack of support services.

CORRECTIONS

In the field of criminal justice, *corrections* is an umbrella term that refers to what happens *after* an individual has been convicted of a crime, sentenced, and placed on supervision (probation) or incarcerated in a county, state, or federal jail or prison. It also includes the subsequent release (parole) from such a facility and a specific period of supervision after release. This process was set up as the best way to assist offenders correct their behavior. Since the mid-1950s, corrections has evolved into a broad field of research and practice that incorporates elements of community supervision, incarceration, rehabilitation, and community reintegration within the scope of the prevailing correctional philosophy and goals. This entry explores the history and goals of corrections, explaining how prevailing sociopolitical thinking influences correctional approaches. In addition, this entry examines the various career and job opportunities available within the correctional system, including challenges and associations for correctional officers.

Correctional Philosophy

The survival of a culture depends on the creation of rules of behavior and a means of maintaining a

social order, typically by agents of the prevailing government. Historically, a society's sociopolitical philosophy advocated punishing and deterring misbehavior that potentially threatened the social order. From the *Code of Hammurabi* (1750 BCE) to the current day, varying methods of *correcting* and deterring misbehavior by various means of punishment have served that function. For thousands of years, such punishment has included torture and branding, dismemberment, public humiliation, whipping, slave labor, imprisonment, and death by various means. The point of these interventions was to create sufficient fear among the citizens as well as those punished (criminals) to deter future misbehaving and instill more motivation to follow the established rules of government-imposed social order.

As civilizations became more complex, the use of extreme punitive methods declined in keeping with the social philosophies of the time (e.g., humanitarianism), and those brought under the jurisdiction of the government for crimes were subject to less brutal means of punishing their behavior and deterring others from committing crimes. Incarceration, rather than execution, became more widespread. By the 18th century, however, religion influenced the development of the idea that crime was a sin and that those incarcerated should be subject to opportunities to change their behaviors by following religious practices of prayer, meditation, obedience, and proper behavior. The concept of rehabilitation while incarcerated became more popular than just incarcerating criminals for punishment. This ideological shift contained the seeds that eventually grew into today's field of corrections: a field that embodies the notions of incarceration as punishment, humane treatment, and rehabilitation.

Since the 18th century, correctional philosophies and goals have varied with the prevailing social and political times as well as the influences of the times on the prevailing criminal justice system. In a very general sense, these variances resulted in oscillations between more or less punishment and more or less rehabilitation and the development and implementation of rehabilitative methods and programs. When the focus was on more punishment, sentences were lengthened and criminals spent longer times incarcerated, often under very unpleasant conditions, with a strong

emphasis on security and behavior control. With a focus on rehabilitation, more emphasis was placed on education, learning trade skills, and treatment for mental illness and drug addiction, to facilitate community adjustment following an inmate's release back into the community.

Goals of Corrections

Four different goals of corrections are commonly espoused: deterrence, incapacitation, rehabilitation, and retribution. Each has received varied levels of public, political, and professional support depending on the sociopolitical influences of the time. As the overarching goal of corrections, deterrence is achieved by various forms and degrees of punishment in keeping with the nature of the crime as well as the prevailing sociopolitical sense of appropriate retribution. The hope is that through retributive punishment and rehabilitation, the individual and others similarly inclined will either resist offending or be deterred from engaging in future criminal behaviors.

Incapacitation most often entails incarceration in a jail (for sentences of a year or less) or prison (for sentences longer than a year). It may also include a period of house arrest, during which an individual must stay in his or her own residence, generally under supervision by a government agency (e.g., police, probation officers). Incapacitation serves both as a means of punishment and contributes to public safety by removing dangerous individuals from society but requires such resources as secure facilities (e.g., jails, prisons, hospitals) and staff (e.g., prison guards, medical personnel).

Rehabilitation represents an attempt to provide an individual with the treatment and skills necessary to adjust to incarceration, take advantage of available treatment and educational programs, and to function more successfully in the community following release from incarceration. Rehabilitation may include the teaching of job skills, education, and treatment for mental illness and drug abuse, and the various types of therapy modalities necessary to implement them (e.g., individual and group therapies).

The fourth goal of corrections is retributive punishment which may include fines, community service, or a period of supervision by a

government agent during which specific rules must be followed (i.e., probation). This may be court imposed in lieu of incarceration. However, a violation of a probationary rule may result in a period of incarceration.

Careers in Corrections

Corrections is a field with abundant opportunities for employment and a career. These opportunities have evolved and expanded since the 1970s as a result of increasing numbers of jails and prisons—both public and private. The United States is the world's leading incarcerator, and employment and career opportunities have evolved to both manage and treat the more than 2 million individuals in today's jails and prisons. These jobs include prison administrators, management positions, prison security, medical staff, mental health staff, social workers, probation and parole agents, teachers, religious staff, groundskeepers, cooks, secretaries, and administrative support staff. Many jobs are obtained and managed through state or federal departments of corrections or privatized institutions.

Challenges

The overarching goal of corrections is to assist the offender to correct his or her behavior so the offender no longer poses a threat to public safety and can be safely reintegrated back into the community. Since research has provided few guidelines regarding how best to meet this expectation, diverse opinions about how to accomplish this task are debated in sociopolitical arenas and contribute to the ideological pendulum swings between punishment and rehabilitation. Most of these opinions center on the levels of effectiveness of the various components of corrections—incarceration, rehabilitation, reintegration, and supervision services—in deterring individuals from initially offending or reoffending. Generally, however, research does not provide definitive answers to situations that are often complex. While incarcerating dangerous individuals removes their threats to public safety, for example, what is the most effective correctional action to take for those who do not clearly pose a threat to public safety, such as nonviolent drug offenders,

individuals who do not pay child support, or those who are mentally ill? One of the significant legislative and economic consequences has been the increased need for more prisons and, another, the increased use of private prisons as a potential means of saving money. This has contributed to a growing private prison industry that is likely to continue to grow.

Working in a correctional facility or in the community as a corrections professional (e.g., probation or parole officer) can be challenging and stressful since the consequences of the prevailing social correctional ideology spills over into that arena. Regardless of one's job or profession, one may work in a correctional system or facility that fails to meet established standards of professional care such as those established by the American Correctional Association, the National Institute of Correctional Health Care, or the international standards of the Nelson Mandela Rules or Bangkok Rules. One may work in an overcrowded facility with limited medical and mental health staff; an overuse of segregation and isolation; poorly trained and/or abusive security staff; and interact with individuals who may be angry, depressed, resentful, cognitively disabled or medically challenged, suicidal, and/or physically dangerous. There may be occasional assaults on both staff and inmates. The security level of a facility (e.g., super maximum, maximum, medium, or minimum), the classification of the inmates housed there, and how security and rehabilitative programs are administered have a large impact on working conditions such as levels of hostility and conflict among both staff and inmates. Another challenge is the potential for being sued for alleged negligence or deliberate indifference depending on one's job role.

In addition to staff, administrators within the correctional system also face a number of challenges. Primary is the need to keep those within a facility—staff and inmates—safe and secure within the scope of applicable standards, while operating the facility or agency within a prescribed budget. Administrative positions are often politically sensitive and may entail occasional contact with political leaders, legislators, the news media, and the public.

With these challenges, a successful career in corrections often entails learning how to manage

the impact of these various stressors in ways that minimize their negative impact on one's physical or mental health and personal life (burnout) while at the same time contributing to the betterment of an offender in the interests of public safety.

Correctional and Professional Associations

There are a number of professional associations with which a correctional professional may affiliate that can provide collegial support, educational opportunities, and practice guidance, depending on one's position and professional interest. Among them are the American Correctional Association, the International Corrections and Prisons Association, the International Community Corrections Association, and the International Association for Correctional and Forensic Psychology. There are also correctional and professional associations at the state and national levels, including the National Association of Social Workers, the National Association of Wardens, the National Association of Wardens and Sheriffs, the Prison Officers Association, and the American Psychological Association. Information regarding these and other related associations and agencies are widely available online.

Final Thoughts

Corrections is the field of study and practice within the criminal justice system that impacts an offender after having been found guilty and sentenced through the criminal court process. It includes offenders being incarcerated in a correctional facility, being provided rehabilitation services for problems such as drug addiction and mental illness, and/or being supervised in their communities by probation and parole agents. There are numerous opportunities for careers in the corrections field that include administration; providing medical, mental health, education, social work, and other rehabilitative services and programs; working in security, maintenance, and a variety of other support services in a facility. Although there are challenges associated with working within the corrections field, there are also rewards, from helping individuals better themselves in ways that contribute to a successful

reintegration into their community consistent with the interests of public safety.

COST-EFFECTIVENESS OF REHABILITATION VERSUS INCARCERATION

Incarceration of offenders has proven to be a serious and persistent problem for criminal justice and public health systems. These systems must balance punishment and rehabilitation while simultaneously dealing with a high prevalence of psychosocial problems among criminal offenders, which contribute to the likelihood of ending up back in prison (i.e., recidivism). The cycle of recidivism is an economically and socially damaging problem and can be partially blamed on a lack of standard protocols for behavioral health, education, and other services both in prison and after release. Central to these challenges are concerns about the economic impact of rehabilitation interventions for offenders. In the face of unprecedented local, state, and federal budget crises, policy makers struggle to identify programs that are not only cost-effective in

reducing recidivism but also save money over time by reducing broader societal costs associated with substance use, criminality, homelessness, unemployment, and other disadvantages faced by criminal offenders. This entry presents data related to adults involved in the U.S. correctional system (during and after incarceration) and highlights some of the programmatic issues associated with attempts at rehabilitating these individuals and thereby reducing reoffending.

The U.S. Adult Corrections Population

The Bureau of Justice Statistics reported that an estimated 6.7 million individuals were involved in the adult correctional system in the United States as of year-end 2015. The number of incarcerated individuals equated to approximately 1 in 36 adults or roughly 3% of the total U.S. population. The overall number of adults involved in the correctional system has shown a decreasing trend over the past few decades, primarily due to reductions in the probation and incarcerated population. The parole population showed a modest increase (1.5%) in 2015. The National Institute on Drug Abuse, through a survey conducted by the U.S. Department of Justice in 2002, has concluded that approximately 70% of state and 64% of federal prisoners regularly used drugs, including alcohol and illicit substances, prior to their incarceration and as many as one in four violent crime offenders committed their offenses under the influence of drugs. Not only do many offenders commit crimes as a result of using substances and in order to finance their substance use but also many incarcerated persons with substance use disorders find it difficult to reintegrate into society upon release from prisons or jails.

In addition to a history of mental illness and substance use, factors such as the seriousness of offenses committed and low socioeconomic status perpetuate the recidivism and reincarceration cycle, also known as the *revolving door* between jail or prison and the community. Based on data from 2005, the National Institute of Justice has reported that nearly two out of three prisoners will be rearrested within 3 years post-release, and nearly three out of four prisoners will be rearrested within 5 years. With respect to total recidivism, more than half of those prisoners will be

rearrested during the first year post-release. These rates are even higher among drug offenders and violent offenders—76.9% of drug offenders and 71.3% of violent offenders with histories of substance use are reincarcerated.

Economic Concerns

According to the Bureau of Prisons, the average cost of incarceration for a federal inmate in fiscal year 2014 was US\$30,620 (US\$83.89 per day). While the average cost per state inmate varies drastically by state, a 2012 Vera Institute of Justice Survey estimates that the average state prisoner costs taxpayers US\$31,286 per year (US\$86 per day). In addition to the direct costs of incarceration, the societal cost of crime includes direct losses to victims, such as medical expenditures and the value of stolen property, policing and legal/adjudication costs, lost productivity, the risk of homicide for certain offenses, and the intangible losses associated with a victim's pain and suffering. Some offenses, such as rape/sexual assault, carry a societal cost per offense of more than US\$200,000. Due to such high societal costs of criminal activity, rehabilitation and reentry programs that generate even modest reductions in crime—especially costly violent offenses—have the potential to be cost saving.

Rehabilitation Programs in Criminal Justice Settings

Rehabilitation programs in criminal justice settings are numerous and target the unique behavioral, social, and environmental needs of the offender population. Many of these programs feature mental health or substance use disorder treatment (e.g., in-prison therapeutic communities for co-occurring disorders); others focus on vocational training, on education, or, more specifically, on reducing the risk of reoffending by addressing criminogenic tendencies (e.g., Risk-Need-Responsivity). These programs have been implemented within correctional institutions, after incarceration, or, in the case of specialty courts, as alternatives to incarceration for nonviolent and/or first-time offenders.

The role of substance use disorder treatment in the rehabilitation process is a major area of focus

among criminal justice and public policy stakeholders, but consensus regarding a standard set of evidence-based treatment models for offenders is unreconciled. Evidence of effectiveness from randomized trials and quasi-experimental studies of treatment interventions for criminal offenders is mixed. Many studies have found that in-prison treatment, for example, is effective in reducing substance use and criminal recidivism in the short run but only for offenders who are engaged in aftercare programs upon release from prison. Other studies have found that differences in substance use and criminal activity between treated and untreated offenders evaporate over time.

Evidence supporting post-incarceration interventions is less tenable. Randomized trials of interventions targeting relapse prevention and improved linkage to substance use treatment services through parole or probation-based case management programs or intensive supervision did not find statistically significant differences in substance use, recidivism, or service utilization among intervention participants relative to standard community supervision. The interventions did show some promise, however, among subgroups of participants such as women offenders or those using specific substances (e.g., marijuana).

Drug courts have a solid base of support among policy makers and researchers in terms of their effectiveness in curbing reoffending. The National Association of Drug Court Professionals cites numerous facts promoting expanded support for these programs. Notably, scientific studies have shown that approximately three quarters of drug court participants remain arrest-free in the 2 years following participation in a drug court program. Moreover, relative to incarceration or other sentencing options, drug courts have been shown to reduce self-reported crime (that may or may not have led to arrest and incarceration) by as much as 45%.

Cost-Effectiveness of Rehabilitation Programs

Expanded implementation of rehabilitation interventions for criminal offenders requires not only clinical evidence of best practices but also consideration for the additional costs and cost-effectiveness of these programs. While economic studies examining corrections-based interventions are relatively scarce, a few studies have estimated the

cost-effectiveness or net economic benefits of rehabilitation programs for adult and juvenile offenders, including Risk-Need-Responsivity, work release programs, vocational training, specialty court programs, and substance use disorder treatment. For instance, using data from randomized trials conducted between 1998 and 2004, studies investigating the cost-effectiveness of in-prison therapeutic communities in California state prisons found that in-prison treatment alone was not cost-effective relative to a no-treatment comparison group, but in-prison treatment plus post-incarceration aftercare was cost-effective in reducing reincarceration and also cost saving when compared to the daily cost of housing an inmate in state prison. Other sources of savings associated with in-prison rehabilitation programs include reduced prison management costs. An economic analysis conducted in 2006 of prison-based therapeutic community programs at the California Substance Abuse Treatment Facility found that compared to non-treatment prison yards, the in-prison treatment yards generated lower administrative costs for disciplinary actions, inmate grievances, and major disruptive incidents resulting in lockdowns.

Benefit-cost analyses have also been conducted on education and vocational training programs, probation and parole-based programs, and specialty courts. An economic evaluation of adult drug court programs in Kentucky, conducted in 2004, found that among program graduates, US\$3.8 in economic benefits were generated for every US\$1 invested in the programs. Drug court evaluations in several other states have demonstrated similar cost-savings results. According to primary evaluations and meta-analyses across numerous rehabilitation programs by the Washington State Institute for Public Policy (updated in 2017), most rehabilitation programs for offenders generate positive net economic benefits. Exceptions include life skills education programs, domestic violence perpetrator treatment, police diversion for individuals with mental illness, intensive supervision for juvenile offenders, as well as policies such as sex offender registration and community notification.

Nonmeasured Cost Savings

Most of the economic studies summarized herein do not capture the full range of outcomes that can be

used to assess the economic benefits of rehabilitation interventions for criminal offenders. The consequences of criminal offending and incarceration impact other domains such as physical and mental health services utilization, employment and educational outcomes, dependence on social services, risky sexual behavior including HIV and hepatitis C risk, and quality of life. If corrections-based rehabilitation programs can be linked to reduced emergency department visits, reductions in criminal activity, improved productivity, and reduced HIV risk, desired changes in many of these outcomes can be translated into dollars and used to calculate the economic benefits and cost savings. For instance, based on estimates using national data, the average cost per emergency department visit (treat and release) is US\$389 (from 2016 data), and the average cost per robbery is US\$45,118 (from 2008 data). If a corrections-based intervention generates on average 20 fewer emergency department visits and five fewer robberies per year relative to a nontreatment comparison condition, this would generate \$233,370 $[(20 \times \$389) + (5 \times \$45,118)]$ in medical and crime-related savings to society.

Policy Recommendations

Any debate that previously existed regarding rehabilitation versus incarceration of criminal offenders has been replaced with a debate about which rehabilitation programs represent the best investments for the criminal justice system. The powerful connections among substance use, crime, and incarceration, coupled with the high costs of imprisonment, indicate there is a potentially cost-saving opportunity to address substance use disorders within the criminal justice population. Most notably, the controlled environment of a prison presents an opportunity to offer substance use treatment and other rehabilitation programs to inmates at a relatively modest cost. As policy makers strive to allocate limited resources across competing programs, better understanding of whether corrections-based rehabilitation programs are both effective and cost-effective is key. Cost-effectiveness analysis is a powerful tool for demonstrating the competing programs that generate the greatest improvement in such desired outcomes as reduced rearrest or reincarceration for the lowest cost. Theoretically, it is expected that more expensive programs will generate greater improvements,

a result that was verified in many of the cost effectiveness studies of in-prison therapeutic community treatment plus aftercare. Studies of probation and/or parole-based interventions for offenders with substance use disorders are less encouraging, but research is more limited in this area and further investigation is warranted.

There are some key findings from the existing economic research on rehabilitation programs for criminal offenders. First, providing rehabilitation programs in correctional settings is generally effective in reducing criminal recidivism and substance use relapse, but these effects may disappear over time. Second, a continuum of care featuring in-prison programs plus post-incarceration reentry and recovery support services is cost-effective. Third, post-incarceration programs for offenders play a pivotal role in determining the overall cost-effectiveness of providing rehabilitation services to prisoners. Fourth, broader economic evaluations of rehabilitation programs should include outcomes such as health services utilization, criminal activity (irrespective of arrests or convictions), social services utilization, and employment to demonstrate the extent to which corrections-based rehabilitation is cost saving over time. Finally, as the science on rehabilitation versus incarceration continues to evolve to include protocols such as screening, brief intervention, and referral to treatment, continuing care/recovery management, and e-health technologies, determining the effectiveness and cost-effectiveness of these approaches as they translate to criminal justice settings must be a national research priority.

COURTS, FEDERAL

The U.S. federal court system enforces federal laws and regulations, by applying and interpreting the Constitution of the United States, profoundly influencing public policy, and resolving important conflicts for any citizen across the country. The federal courts derive their power directly from Article III of the U.S. Constitution, and this power extends across the entire nation and the states. Article III states in part that “judicial power shall extend to all cases, in law and equity, arising under this Constitution, the laws of the United States, and treaties made, or which shall be made, under their authority.” page 3.

About 1 million cases are filed annually within the federal courts, and although a seemingly high number, the federal courts’ authority is significantly limited compared to state courts’. The variety of cases in federal court include disputes over the constitutionality of a law; disputes between two or more states; matters involving ambassadors and public ministers; specific interpretations and enforcement of federal laws, such as bankruptcy and immigration; and treaties with foreign countries.

Jurisdiction defines whether a court has the power to adjudicate a case. A court’s jurisdiction can be over a person charged with violating a federal law punishable as a crime or can be civil disputes. In the civil context, a substantial factor on deciding whether a claim can be brought in federal court depends on its subject matter jurisdiction, divided basically into federal question jurisdiction, diversity jurisdiction, and supplemental jurisdiction.

Federal question jurisdiction encompasses issues concerning the U.S. Constitution or other federal statutes or regulations. *Diversity jurisdiction* authorizes federal courts to hear disputes for which the opposing parties are each citizens of different states. When no federal question is involved, diversity jurisdiction allows citizens with distinct state citizenships to have a fair and neutral forum to have their cases heard subject to limitations in the *amount in controversy* of US\$75,000 or more. *Supplemental jurisdiction* gives authority to federal courts to adjudicate a claim that would typically not fall within their jurisdiction but is related to a claim already before the federal court. This type of jurisdiction is discretionary but usually involves one claim falling within federal question jurisdiction as well as a related state court claim.

On a basic level, the majority of cases in federal court start at the district court level, which serves as the trial court in the federal system. There are also specialty courts to handle matters such as tax, immigration, and bankruptcy. The size of the area served and the location of a district court varies throughout the nation based on population. The district courts have original jurisdiction over most categories of federal cases, including both civil and criminal. As of 2018, there are 94 district courts in 89 districts in the 50 states and territories. As of 2017, there were 667 permanent district judges authorized by Congress.

A party unsatisfied with the decision at the district level is afforded a limited appeal to 1 of the 13 appellate courts divided into 12 regions. Strict

procedural limitations apply to appeals to these U.S. Courts of Appeal who sit just below the highest court of the land—the Supreme Court. The appellate court system is named the U.S. Court of Appeals for the Federal Circuit. It hears specialized cases such as those involving patent laws or cases decided by the U.S. Court of International Trade and the U.S. Court of Federal Claims. Once the appellate circuit court has issued its decision on the appeal, the case could be remanded back to the district court for further consideration, a party could request a rehearing of the case, or the party could appeal directly to the Supreme Court by requesting a *writ of certiorari*. As of 2017, there are 179 federal judges in the courts of appeal.

The Supreme Court of the United States, known as the *highest court in the land*, primarily is an appellate court of last resort, hearing appeals from both state supreme courts and lower federal courts. Four of the nine Justices of the Supreme Court must choose to issue a writ of certiorari, allowing the Supreme Court to consider making a decision on a case. Each year only a small percentage of cases appealed to the Supreme Court receive review. The Court limits its consideration to those cases involving the most important questions of interpretation and fair application of the U.S. Constitution and federal law. The Supreme Court has very limited *original jurisdiction* on matters they decide from beginning to end.

All federal judges, at the district and appellate levels, serve with life tenure being nominated by the President of the United States and confirmed by the U.S. Senate. The federal court system is complicated and possesses immense power and authority. The federal court system enforces and interprets the U.S. constitution and laws, ensures and protects citizens' rights, and profoundly influences public policy.

COURTS, INTERNATIONAL

The term *international courts* covers many institutions with different structures and functions. Common among them is that they adjudicate disputes based upon principles of law rather than the wealth or political power of participants and thus are judicial bodies. Another commonality is that they have been created by agreements between states and are therefore international. Most international courts decide disputes occurring between states rather than individuals. For example, the International Court of Justice is the principal judicial organ of the United Nations. Its main function is to resolve legal disputes among members of the United Nations. Individuals cannot be parties to legal proceedings at the International Court of Justice.

One of the few bodies of international law that directly affects individuals is international criminal law. Certain acts by individuals, such as genocide, war crimes, and crimes against humanity, are violations of international criminal law and can

result in criminal sanctions such as incarceration. While violations of international criminal law can be prosecuted by national legal systems, a number of international courts have been created to prosecute such violations, particularly in situations where individual states are unable to carry out prosecutions on their own. These courts have generally been referred to as *international criminal courts* (ICCs) with one, the ICC, recognized as the most important. This entry traces the development of ICCs with a particular focus on the ICC.

The Development of ICCs

ICCs developed in tandem with international criminal law. While some aspects of international criminal law had been developed prior to World War II, the horrors of that conflict, particularly the Holocaust, spurred a rapid expansion of the law. It also gave rise to the first ICC—the International Military Tribunal at Nuremberg—created by the Allies after World War II to prosecute senior Nazi leaders.

Nearly 50 years later, the United Nation Security Council created two more ICCs: the 1993 International Criminal Tribunal for the former Yugoslavia in response to the widespread mistreatment of civilians during the civil war that took place following the disintegration of Yugoslavia and the 1994 International Criminal Tribunal for Rwanda in response to the genocide there. Both courts were modeled on the International Military Tribunal and prosecuted individuals for violations of international criminal law.

The International Military Tribunal, International Criminal Tribunal for the former Yugoslavia, and International Criminal Tribunal for Rwanda are generally viewed as having been successful, though limited because they were impermanent responses to particular atrocities. With a permanent international court, atrocities could be addressed no matter where they occurred without needing to create a new institution in response to every crisis. After many academics and civil society groups pressed for the creation of such a permanent court, the ICC was established.

The ICC

The ICC was created by a treaty known as the *Rome Statute*. It began operation in 2002 and, by

2016, included 124 states as parties to the Rome Statute and members of the ICC—roughly 65% of the countries in the world. However, a number of powerful countries, including the United States, Russia, and China, have refused to join the ICC, objecting to an international court having jurisdiction over their citizens without their consent.

The ICC, located in The Hague, the Netherlands, is a permanent international court with jurisdiction over serious violations of international criminal law, including war crimes, crimes against humanity, and genocide. However, it has a number of limitations to its authority. First, it investigates and prosecutes only individuals. The court has no authority to adjudicate the responsibility of states for the commission of international crimes. Second, its geographic jurisdiction is limited. While some supporters hoped it would have jurisdiction over crimes committed anywhere in the world, it is mostly confined to crimes committed upon the territory of its member states.

The ICC was never intended to prosecute every violation of international criminal law. Rather, it was created as a court of last resort to prosecute violations that would otherwise go unpunished. Thus, the court cannot prosecute anyone unless the national jurisdiction that would otherwise have jurisdiction over the violation is either unable or unwilling to conduct the prosecution on its own. The ICC is meant to complement, rather than replace, domestic prosecutions.

Internally, the court is composed of various organs that operate independently. The Office of the Prosecutor is responsible for investigating and prosecuting violations of international criminal law. The Judicial Division contains the judges who decide whether the individuals charged by the prosecution are guilty. The Assembly of State Parties is composed of all the states that are members of the ICC and is responsible for deciding on the budget of the court, which is then paid for by the member states. The Registry provides support services to the other organs.

The Rome Statute contains numerous due process guarantees for defendants. For example, all individuals charged by the ICC are presumed innocent, and defendants have the right to legal representation and to present witnesses and

evidence to challenge the witnesses and evidence presented by the prosecution. If the accused is indigent, the court will provide funds to hire defense counsel.

In order to convict the accused person, the judges of the Trial Chamber must be convinced of the guilt of the accused beyond a reasonable doubt. There are no juries at the ICC. All decisions, including the determination of guilt, are made by judges. A convicted defendant may be fined, ordered to forfeit the proceeds of the crime, or sentenced to a maximum term of life in prison. The death penalty is not available. If convicted, the accused has a right to appeal the decision of the Trial Chamber to an Appeals Chamber.

The Future of the ICC

Much of the academic debate about the ICC has centered on whether it is successful. Detractors often point to the small number of investigations and prosecutions and ask how a court that tries so few cases could have a meaningful impact on the world. Supporters tend to focus on the fact that a majority of states have joined the ICC, which they say shows that most states support the goals of the court. Ultimately, part of the problem is that there is little agreement about what success means or how to measure it. Another problem is that the ICC has only been in operation since 2002. It may take several decades before any significant impact of the court can be seen.

COURTS, STATE

A state court is a court in one of the 50 state judicial systems of the United States. State courts vary widely in scope and structure. Most state courts and their laws are generally patterned after the English common law, with the exception being structure and substance originally developed in civil law. Each state has its own system, and with a few exceptions, most of the systems embody similar structures and levels of authority.

Over 50 million nontraffic cases are filed in state courts each year, while only about 1 million are filed in federal courts annually. Typically, state courts can hear almost every type of case, conflict, or complaint—both civil and criminal—based upon violation of the state's constitution or the laws and regulations of the state created by the state's legislative or regulative bodies under the authority of the state's constitution. Examples of a few legal matters that state courts will not hear involve bankruptcy, immigration, patents, copyrights, violations of federal criminal law, and other conflicts involving the interpretation or fair application of federal law heard in the federal courts.

Various levels of criminal violations generally appear in state courts, from petty or lower level crimes usually labeled as misdemeanors with punishments generally limited to local incarceration or fine to serious crimes labeled felonies with punishments involving incarceration for longer periods of time, substantial fines, and/or serious long-term collateral consequences. In the civil dispute context, a substantial factor on deciding where a claim can be brought in the state court system depends on the court's jurisdiction (i.e., the court's power to adjudicate a case), which is almost always tied to the limited subject matter jurisdiction of the court or to the amount in controversy between the parties.

Although each state may label their courts differently, the basic court in a state is its trial court. Whether labeled circuit courts, superior courts, district courts, trial courts, chancery courts, or courts of common pleas, these trial courts generally have broad general jurisdiction over matters both civil and criminal and are usually located in a county seat and operate as the basic judicial entity for disputes. Although the courts may be in

multiple locations or divisions in the larger cities, the basic structure is the same. Also popular throughout the state court system is the use of specialty courts presided over by judges—such as magistrates, associate judges, and court masters—who are hired by the trial judges to perform specific duties in order to ease the burden that number of cases filed in the state courts bring upon the orderly disposition of justice.

Typically, judges in the trial courts are elected politicians, whereas the specialty judges are usually hired for a specific purpose and often answer to the elected judges and serve at will. There is an ongoing discussion as to whether the election of trial judges is good for the system or whether appointment would remove politics from the administration of justice. Some states have attempted reform by making the election of judges nonpartisan, whereas others use elections only for retention purposes.

Most state systems include low-level trial courts—often called *municipal courts*, *justice of the peace courts*, *magistrate courts*, or *county courts*—that preside over civil disputes involving petty and lesser amounts and low-level crimes, including the violation of misdemeanor crimes, municipal ordinances, and regulations. In some states, these low-level trial courts may be presided over by nonlaw-trained, layman judges who are elected to office. Many states have attempted to create a higher level trial court often by using the term *at law* in the courts' description. These courts are presided over by law-trained judges and typically are political positions. These courts handle more complicated matters considered best reserved for the lawyer judge. In general, the main trial court in a county is that created by the constitution of the state; however, for the specific jurisdiction of each level of trial court, state law should be consulted.

Many states include a regional intermediate appellate court to hear intermediate appeals from the trial courts. Some states do not have this system and use intermediate appellate courts only when the cases are assigned by the state's highest appellate court. These intermediate courts may carry the names court of civil appeals, court of criminal appeals, court of appeals, appellate court, district court of appeals, intermediate court of appeals, court of special appeals, superior court,

or other names that indicate their role in the system.

Each state has a court of last resort. Typically called the *supreme court*, the role of this court is to have statewide jurisdiction in the resolution of matters not resolved to the parties' satisfaction at the trial court or intermediate appellate level when there are legitimate issues showing error in the lower courts. As with the federal system, not all state appeals make it to the supreme court of the state, as such appeals are usually subject to the court's discretion to hear the dispute. A few states have a separate court of last resort for criminal matters, but most states' supreme court hears both civil and criminal matters.

Worthy of note are the tens of thousands of employees of these courts working as magistrates, associate judges, court masters, probation officers, court clerks, law clerks, court reporters, bailiffs, administrators, and other court officers, who are essential to the operation of the state judicial system.

CRIME LINKAGE ANALYSIS

Crime linkage analysis (or linkage analysis) is a technique used by police practitioners to assist them in determining whether multiple crimes have been committed by the same offender. The term is typically used to refer to techniques that rely on behavioral information to make linkage decisions rather than physical evidence, such as DNA, fingerprints, or fibers. Linkage analysis is thought to rely on two assumptions: that offenders exhibit similar behaviors across the crimes they commit

(*behavioral consistency*) and that not all offenders commit their crimes in the same way (*behavioral distinctiveness*). Under conditions where some degree of behavioral consistency and distinctiveness exists, linkage analysis should be possible. This entry focuses on the importance of linkage analysis, the various types of linkage tasks that police practitioners encounter, research on linkage analysis, and the use of linkage analysis in court. The entry ends with a brief discussion of research priorities.

Importance of Linkage Analysis

Linkage analysis has been used by the police since the late 1800s. Despite what the public might think, physical evidence is often not available at crime scenes. Thus, to determine whether multiple crimes have been committed by the same offender, it is often necessary to rely on the behaviors exhibited by offenders. However, because it is rarely possible to observe offenders' behavior directly, police practitioners must determine how an offender behaved by visiting crime scenes or by interviewing victims and witnesses.

If used successfully, there are many advantages associated with linkage analysis. For example, when multiple crimes are connected to the same offender, additional evidence from across the crimes becomes available, which can potentially help investigators solve the crimes (and secure harsher sentences for offenders). Investigating multiple offenses as a single series, rather than as several independent crimes, also allows limited police resources to be used more efficiently. Finally, accurate crime linkages allow the police to use other investigative techniques such as geographic profiling that can only be used effectively when an unknown offender's crimes have been successfully linked.

Types of Linkage Tasks

Police practitioners encounter a variety of linkage tasks. The first task involves searching a large database of offenses for pairs of crimes that have been committed by the same offender. The second task involves being provided with an *index* crime (e.g., by an investigator) and searching a large database of offenses for possible linkages to that index crime. The third task involves being provided with a small number of crimes and

determining whether any of those offenses are likely to be linked. In many jurisdictions, these tasks are performed by different types of practitioners using different analytical procedures.

The first two tasks are commonly carried out by practitioners who have been specially trained to use computer databases, such as the Violent Crime Linkage Analysis System (ViCLAS). ViCLAS was originally developed in the 1990s by the Royal Canadian Mounted Police, but the system is now used around the world and is generally considered the gold standard of computerized crime linkage systems. ViCLAS is a computer database that stores information about particular types of crimes (e.g., interpersonal violent crimes). Information about the crimes (e.g., victimology, the offender's method of operation [*modus operandi*], forensic information) is recorded by the investigators of those crimes and ultimately downloaded into the database. Trained ViCLAS analysts use various query strategies to search the database in an attempt to identify potential crime linkages. If potential linkages are identified, the investigators associated with the relevant crimes are notified.

The third task is often performed by profilers or behavioral investigative advisors as they have come to be called in some jurisdictions. These individuals draw on their experience, expertise, and relevant research to help them determine whether two or more crimes within the prescribed set of offenses under consideration are the work of the same offender. These individuals will often look for patterns in offenders' *modus operandi*, including the times and locations of the crimes. They may also attempt to identify unique behavioral signatures, which indicate that the crimes under examination may have been committed by the same offender (i.e., unusual features of the crime that were not necessary for the commission of the crime, such as things that were said to the victim by the offender).

Research on Linkage Analysis

Despite the fact that linkage analysis is an important investigative technique, only since the late 1990s have researchers dedicated serious attention to the topic. Research in this area primarily focuses on two related issues: determining whether the assumptions highlighted earlier (*behavioral consistency* and *distinctiveness*) are valid and determining

whether crime linkages can be established with a reasonable degree of accuracy (usually using some sort of statistical or computational procedure). Given the nature of the linkage tasks described, two primary approaches have been used to examine these issues, both relying on solved crimes so that ground truth can be confirmed (i.e., whether crimes in a sample have in fact been committed by the same offender). The first approach relies on a pairwise linkage task, whereby an attempt is made to determine if it is possible to accurately determine whether pairs of crimes have been committed by the same offender or different offenders. The other approach focuses on the ability to assign index crimes to their correct crime series (i.e., predicting series membership). Success with either approach is taken as a sign that serial offenders exhibit a reasonable degree of behavioral consistency and distinctiveness across their crimes.

Research using the pairwise linkage task has attempted to identify the conditions under which pairwise linkage decisions can be accurately made. Factors examined by researchers using this approach include statistical procedure used to make predictions, type of crime under consideration, behavioral variables used to calculate across-crime similarity, coefficient used to quantify similarity, and the country where the crimes occurred. This research generally shows that it is possible to accurately distinguish between crime pairs committed by the same offender versus different offenders, although a number of factors influence the degree of accuracy achieved.

The most common measure of predictive accuracy in these types of studies is the area under the receiver operating characteristic curve (AUC). The AUC can range from 0 (total inaccuracy) to 1 (perfect accuracy). Studies that have examined the pairwise linkage task typically report AUCs in the acceptable (.70 to .80) or excellent (.80 to .90) range, although outstanding AUCs (>.90) are also sometimes found. Two of the most important factors that impact predictive accuracy are the type of crime being examined and the behavioral variables used to make the predictions. Linkage accuracy tends to be higher when interpersonal crimes are examined (e.g., rape vs. burglary) and for offense behaviors that appear to be less situationally determined (e.g., where and when an offense takes place vs. how an offender interacts with their victim).

Research that has focused on predicting series membership also indicates that offenders exhibit a degree of behavioral consistency and distinctiveness, thus allowing for reasonably accurate linkage decisions to be made. The AUC is used less often in these types of studies. Instead, linking accuracy is more commonly gauged by determining the percent of index offenses that can be assigned to the correct crime series. Across a wide range of crime types, including serial arson, rape, and homicide, these studies indicate that crimes can be assigned to their correct series with greater-than-chance-level accuracy. In these studies, researchers sometimes identify scales that underlie crime scene behaviors (e.g., reflecting different types of violence exhibited in serial homicide behavior). They then use scores derived from these scales as independent variables, and the series an offense belongs to as the dependent variable. Using various statistical procedures, prediction accuracy levels as high as 60% have been reported in these types of studies (i.e., in some cases, 60% of index crimes can be correctly assigned to the correct crime series).

Crime linkage researchers usually explain the results from their studies by drawing on personality theories, which support the contention that offenders are likely to exhibit behavioral consistency and distinctiveness across their crimes. For example, some models of personality suggest that behavioral strategies will be activated in response to internal (e.g., sexual fantasies) and external (e.g., victim reaction) triggers encountered by offenders across their crimes. These strategies are theorized to be relatively consistent throughout a crime series because the same strategies are likely to be activated across situations deemed similar by the offender, especially if these strategies have previously enabled the offender to fulfill the offending goals. Offender distinctiveness in behavioral responses to the same triggers is thought to result from the fact that offenders will understand and process information differently depending on their own psychosocial, biological, and/or learning histories (e.g., offenders may have biases that cause them to interpret cues in a particular way, such as hostile attribution biases that lead some offenders to interpret ambiguous behaviors on the part of others as hostile).

Linkage Analysis in Court

While linkage analysis is rarely used as evidence in court, its use appears to be increasing, especially in some countries (e.g., South Africa). When linkage analysis is presented in court, the testimony is usually provided with the intention of demonstrating that certain crimes are the work of one individual (the defendant). Academic researchers, legal scholars, and police practitioners debate whether linkage analysis testimony should be admissible in court. Most of the debates focus on whether such testimony can meet relevant admissibility standards. For example, some researchers have argued that linkage analysis testimony fails to meet the Daubert criteria, which make up the admissibility standard used in certain parts of the United States (and form the basis of admissibility standards in a number of other countries). The Daubert criteria essentially require that expert testimony rests on a reliable foundation of research and is based on scientifically valid principles. Other individuals, especially those who have presented linkage analysis in court, argue that linkage analysis testimony, when presented appropriately, can be a useful tool during a trial. As the amount (and quality) of research on linkage analysis continues to grow, support for the use of linkage analysis in court may also increase.

Ongoing Research Priorities

Crime linkage research is difficult to conduct, and most of the research being carried out is highly artificial. For example, most studies rely exclusively on samples of solved serial crimes. However, police practitioners are tasked with trying to link unsolved crimes, which may differ from crimes that have been solved through investigative work (e.g., serial crimes may be solved in the first place because the offender responsible for the crimes displayed a particularly consistent and distinctive modus operandi, which was recognized by investigators). Researchers are actively trying to identify ways to make crime linkage research more operationally relevant, and some advances have been made. For example, a small number of studies have sampled solved and unsolved (but DNA-linked) crimes. These studies still report levels of linkage accuracy that exceed chance, and some of the AUCs found in these studies are comparable to

those reported in other, less realistic research. This suggests that studies characterized by lower levels of ecological validity (i.e., realism) may still provide results that have value in operational settings. More efforts to improve the quality of crime linkage studies are needed.

While crime linkage research has suggested it is possible to use a range of statistical procedures or computational algorithms to accurately determine the linkage status of crime pairs or predict series membership, very little research is being conducted in field settings. Because of this, researchers do not yet know whether the crime linkage methods they have developed can be used in operational settings to improve the linkage accuracy achieved by police practitioners or how these methods can be used in conjunction with common crime linkage databases like ViCLAS. It is essential that field research be conducted to determine how the statistical and/or computational tools being developed by researchers can best support the decisions made by police practitioners who are charged with the task of linking unsolved crimes. The development of initiatives such as the Crime Linkage International Network, which brings together researchers and practitioners from the field of crime linkage analysis, will contribute to such efforts.

CRIME MAPPING

Crime mapping involves the use of geographically referenced data to understand the distribution of crime and other phenomena across the environment. The goal of examining spatial characteristics is to determine relationships between crime and other factors that contribute to its presence. Crime mapping has been a driving force behind the development of many criminological and policing theories. Its history and application reveal the powerful influence that mapping has had to transform the way crime is understood and examined.

Evolution of Crime Mapping: From Rough Macro to Detailed Microanalysis

The oldest known crime maps were created in Europe as early as the 1820s. Adriano Balbi and André-Michel Guerry, for example, studied the relationship between education and crime across regions in France in 1829. The practice spread to other parts of Europe throughout the 1800s to display crime rates across large regions. Because maps were created on a very macroscale, crime theories explained patterns aggregately and with limited precision.

Beginning in the 1900s, sociologists at the University of Chicago began producing within-city maps to examine delinquency and its relation to other physical and social factors in urban communities. In the 1920s, Robert E. Park and Ernest Burgess studied social problems in Chicago showing that cities followed a developmental pattern of concentric rings radiating from the city center. Park and Burgess found higher crime rates just outside the city center, where high residential mobility and poverty left the area disorganized and prone to crime and other disorder problems. This urban ecological approach—based on what now seem to be very large chunks of Chicago—set the stage for later researchers to examine smaller units within cities.

Using 77 community areas within Chicago, Clifford Shaw and Henry McKay compared 1940s' mapped crimes and locations of delinquents' residences. They found that even when delinquent children moved out of the area, high crime rates persisted. This suggested something wrong with the community area itself: a neighborhood effect termed *social disorganization*. While this was a giant step forward in measurement and criminological theory, mapping was a very expensive enterprise. These early researchers lacked modern computers and often relied on crude calculating machines. They needed to draw maps by hand and produced limited statistical analysis of large community areas averaging several thousand residents each. Two problems hindered rapid theoretical and empirical progress during this period: (1) using smaller units of analysis required enormous effort and (2) maps were not easily changed or queried. For example, some researchers used pin maps to visualize crime locations within the city. To examine crime patterns over time, a photograph was taken at Time 1, then all pins were removed and replaced with crime locations at Time 2—an extremely tedious process.

As early as the 1960s, however, some researchers began to use large computers to create maps in St. Louis, MO. Creating crime maps using these large mainframe computers was time consuming and required many people to code and keypunch cards that would be entered into the machine. Program languages were crude and inefficient. Once completed, computer maps rolled out of large line printers with low resolution, not suitable for displaying point data. Computerized base maps needed to be digitized one by one and were not yet part of a general library. Nonetheless, computers allowed researchers to quickly map different phenomena within the same area, once a base map was created. These maps focused on census tracts, with more detail than found in Shaw and McKay's work, yet still relying on what today are viewed as large spatial units with low resolution.

As computer technology improved in the 1970s and 1980s, researchers began to focus on criminal events rather than offenders. Paul and Patricia Brantingham joined a few crime geographers theorizing linkages between crime patterns and human-place interactions. Cleaner data sets and advances in cartography allowed for crime events to be placed in a spatial context, linked to home, work,

shopping, entertainment, and other activities. Initially, these detailed crime maps were limited to small sections of a city. Improvements in census geographic coding during the 1980s allowed block data to be analyzed for entire cities. To use a noteworthy example, Dennis Roncek and his collaborators learned that taverns and high schools increased crime on nearby blocks in Cleveland. Again, smaller analysis units helped increase the precision of crime mapping and sharpen crime analysis.

During this time, geographic information systems (GIS) became available for experimental crime mapping in police departments. However, it was not until the 1990s that significant improvements to computer technology—hardware and software—brought crime mapping to fruition. The age of dynamic mapping surpassed that of pin maps as desk computers replaced prohibitively large mainframes for mapping. Powerful processors, laser printers, and GIS software could all be used to navigate large amounts of data at rapid speed. Geographically referenced data became widely available and could be quickly queried, analyzed, and visualized on desktop computers. With technology becoming more practically affordable, the U.S. National Institute of Justice launched a series of federally funded projects in the mid-1990s to proliferate the use of crime mapping for public safety. Researchers and police departments seized the opportunity to implement these innovations, linking them to policing practice. Crime control theory became increasingly based on spatiotemporal analysis and the linkages between theory and practice thickened.

During the 2000s, block analyses improved and were supplemented with analysis of smaller block faces or segments, specific addresses, and even point locations. David Weisburd and others learned from such analyses that a large proportion of crimes occur in a small proportion of places. Crime incidents could now be analyzed as points in relation to one another and other very local environmental features (e.g., individual bus stops). Many studies utilized spatial statistics to identify hot spots, or clusters, of criminal activity. With knowledge of hot spots, police could target crime control efforts, and researchers could examine related social and physical features with increased precision. Moreover, improvements in crime data, hardware, and software now allowed police and university researchers to study how crime risks

shift by hour of day and day of week and to disaggregate various types of crime.

Examining this abbreviated history of crime mapping demonstrates how technology has been a catalyst for greater precision in both mapping and analysis. Data units over history evolved approximately as follows: nations → provinces → social areas → census tracts → blocks → addresses and points in space. Researchers have increasingly studied individual crime events and how these relate to nearby circumstances. Better computer hardware and software allowed researchers to provide greater detail of understanding. This in turn helped theorists to sharpen their ideas about crime and to guide further analysis. Refined and disaggregated information provides clues for crime detection, suppression, and prevention.

Applications of Crime Mapping

Crime theory, vis-à-vis mapping, has provided two general assumptions about the spatial nature of criminal activity: (1) all crime events occur in a specific place and (2) the locations of crimes are not randomly distributed across the environment. With this knowledge, researchers ask why crimes occur at a specific place and not at others. Law enforcement officers and analysts ask how they can prevent crime from occurring at a specific place without allowing it to spread to others. These questions have been used to develop crime and crime control theory.

Theories of Crime

Crime mapping has responded to modern capabilities and partially shifted its theoretical focus since the Great Depression when social disorganization theory defined the local area in terms of several thousand people, emphasizing general social characteristics such as poverty and unemployment. Although abandoned property, land use, and other aspects of the sociophysical environment were also noted, these were not separated from the larger social matrix.

With more detailed crime mapping available, a family of theories began to focus on very local crime within very local settings. These theories were united by Paul and Patricia Brantingham, using the term *environmental criminology*. People engage in habitual behaviors throughout the

course of the day. Traveling to work, shopping, entertainment, and back home creates an activity space where individuals are familiar with their surroundings. Opportunities for crime occur when the activities of potential offenders overlap those of targets. Crime mapping can identify where those intersections commonly occur, their correlation with physical and social features, and what can be done to minimize opportunities for criminal behavior at those times and places.

Crime Control Theories

Herman Goldstein developed the idea of *problem-oriented policing*, which urges police to focus less on case-by-case response and more toward linking related cases to understand their common local problem. For example, if *Joe's Bar* is generating most of the local crime problems, then its regulation by liquor authorities and police becomes strategic for local crime control. Thus, crime pattern analysis and detailed crime maps serve an operational purpose.

In this way, crime control theories and crime mapping can influence the way law enforcement operates. Law enforcement agencies employ crime analysts who utilize GIS to collect, organize, maintain, analyze, and present these data to direct public safety initiatives and to guide local police officers. Crime mapping techniques can be used to describe the locations of criminal activities, guide allocation of police resources, and link crime to specific contexts (e.g., mismanaged bars, specific public housing blunders). Crime analysts can employ spatial statistics and maps to identify crime clusters, investigate crime patterns, evaluate police interventions, and examine other factors that may relate to crime.

James Q. Wilson and George Kelling introduced *broken windows theory*, suggesting that low-level crime and disorder problems contribute to more serious lawlessness if left unchecked. Although their idea preceded the full development of local crime mapping, today's *hot spots policing* makes extensive use of crime mapping to guide order maintenance efforts. Crime mappers identify clusters of crime and disorder using spatial statistics to distinguish these clusters from seemingly random or unusual crime events. Police resources are directed to these crime-ridden areas to suppress the problem. A 2014 review by Anthony Braga and colleagues supported the

notion that policing hot spots resulted in crime and disorder reduction in targeted places. The efforts were shown to diffuse crime prevention benefits into surrounding areas as well. The location (and time) of hot spots often varies for different types and modes of crime. For example, nighttime burglaries occur in downtown areas (e.g., commercial buildings), but daytime burglaries happen most frequently in residential areas. Determining the location of hot spots often requires baseline knowledge of criminal motivation and patterns.

Geographic profiling is an investigative tool for detecting serial offending developed by Kim Rossmo, which is widely applied. Criminals have been found to follow predictable patterns in the same way that predators such as lions or sharks hunt for prey. For example, the geometric arrangement of crime locations contributes to understanding a criminal's search pattern and method for attack. Using crime mapping techniques and algorithms, geographic profiling identifies patterns in offending and helps police narrow the search radius when looking for serial offenders. *Situational crime prevention*, defined by Ronald V. Clarke, includes five ways of reducing crime opportunities: increase the effort, increase the risk, decrease the reward, reduce provocation, and remove excuses. Clarke suggests that crime prevention efforts should consider how offenders think and use that information to interfere with their actions, including their access to crime locations. Crime mapping is also used to evaluate the effectiveness of crime control efforts. With the implementation of GIS into police operations, large amounts of data are collected, maintained, and analyzed by crime analysts. Combining GIS with management approaches (e.g., *CompStat*) allows police organizations to monitor public safety initiatives. For example, geographic positioning system receivers can be installed on police vehicles to collect information about patrol routes and times. Comparing this information with large amounts of crime location data can determine the effectiveness of current policing efforts and suggest future approaches.

CRIME PREVENTION, POLICIES OF

Crime-prevention policies encompass a wide range of programs, interventions, technologies, and strategies. Unlike crime-control initiatives, which concentrate on reducing the impact of crimes that have already occurred, crime-prevention efforts work preemptively. Crime prevention in the United States originated in the wake of the historic rise in crime during the 1960s and with the public's ensuing belief that the criminal justice system was failing to protect law-abiding residents and to punish or incapacitate (i.e., lockup) criminals. The widespread assumption that crime-control strategies were ineffectual led to the call for preventive options to supplement, complement, or supplant the traditional (largely reactive) anti-crime measures of the police, courts, and corrections.

The effects of criminal victimization can be long term and even life altering. Victims of violent crime can suffer serious injuries, leading to lost workdays and income as well as extensive medical

bills and incalculable pain and suffering (physical and emotional). The costs of arresting, prosecuting, convicting, and punishing offenders run in the tens of billions of dollars each year. In high-crime neighborhoods, due to a fear of crime, residents often avoid interacting with neighbors or venturing out of their homes at night. Violent crime, in particular, diminishes the quality of life in families and neighborhoods and can collectively traumatize communities and engulf them in fear. Given the enormous social, economic, and psychological toll of crime, many consider implementing crime-prevention policies to be imperative.

At the federal level in the United States, the President's Commission on Law Enforcement and Administration of Justice (1967) and the National Commission on the Causes and Prevention of Violence (1969) issued a series of recommendations demanding more ambitious and innovative strategies to combat crime. Since then, numerous crime-prevention enterprises have been created to make the streets safer. These efforts can be categorized roughly in terms of their focus on communities, situations, or people (children, parents, adults in general, and offenders). The individuals who implement these efforts also vary, involving many different agents of change, such as local residents, teachers, parents, police officers, and treatment providers. In some instances, crime prevention relies on technology, for example, alarm systems, surveillance cameras, street lighting, and tracking devices in phones and cars. This entry describes the various targets and effectors of crime-prevention policies and practices in the United States.

Community Crime Prevention (Entire Neighborhoods)

Root Causes of Crime

The President's and National Commissions' recommendations ushered in a new era of anti-crime programs and changed the prevailing crime-fighting narratives and paradigms. No longer dependent on the formal agents of authority and enforcement, crime-prevention policies encouraged citizens to cooperate with police in the coproduction of neighborhood safety and invited nonprofit organizations to the forefront in the battle against crime. No longer incident-focused

or reactive, crime-prevention efforts became broad based (e.g., entire inner-city communities) and focused on the root causes of crime (e.g., unemployment, social inequality, and undereducation). These efforts were also sweeping—directed at large geographic areas—and were theoretically informed. For example, the Chicago Area Project (launched in the 1930s and active as of 2017) endeavored to alter the characteristics of communities, such as pervasive social disorganization and community disintegration. Such conditions are correlated with fear of crime and physical and social disorder, all of which render neighborhoods less livable and less safe.

An early incarnation of community crime prevention was the Mobilization for Youth Program. Founded in New York City in the 1960s, it included a variety of interventions designed to increase economic opportunities and decrease the marginalization and disenfranchisement of inner-city residents. At the core of its philosophies and prescriptions was the proposition that social services and social-action groups could empower people to rise above their impoverished conditions through the pursuit of legitimate opportunities instead of through involvement in illegal activities, antisocial networks (e.g., gangs), and alternative (i.e., underground or shadow) economies: selling drugs, stolen property, and prostitution.

Inclusive Community Efforts

In order to reduce crime, neighborhood-based crime-prevention programs or strategies are designed to change the social infrastructure, culture, or the physical environment of a location. Community-based models are quite diverse, ranging from neighborhood-watch programs to urban or physical-design modifications (e.g., alley gating to impede the ingress and egress of criminals). They can also be widely embracing and multidisciplinary, seeking to engage residents, faith-based organizations, and local government agencies in addressing factors that contribute to neighborhood disorder, delinquency, and crime.

Fighting crime can also involve community building. A shared sense of unity, cohesion, territoriality, and support from the community as a whole (i.e., collective efficacy) fuels anti-crime sentiments and efforts. Communities experience

the damaging effects of crime to varying degrees. Some neighborhoods never exert serious, determined responses to public disorder and crime because they lack the capacity (i.e., social and economic capital) to do so. Neighborhoods with higher income residents who embrace middle-class values and are on the tipping point of more serious crime problems tend to be more active in efforts to combat street crime than are lower-class neighborhoods inundated with crime problems.

Reductions in Disorder and Decay

A sense of solidarity within the community can reverse the downward spiral of neighborhood disorder and decay. For example, groups of residents in block clubs and neighborhood-watch programs have joined together to clean up abandoned lots and implore the city to tow abandoned cars and shutter abandoned buildings. These are *sights* and *sites* that can encourage crime by leaving residents and offenders with the perception that the neighborhood is declining and drifting toward normlessness. This perception weakens the social fabric and invites incivilities that embolden offenders to become more active in their criminal pursuits. Concerted steps help residents become increasingly assertive and empowered, enabling them to restore a sense of general safety and to begin using their streets again, this time with less fear. The most effective community prevention programs concentrate solely on local community issues. Community anti-crime efforts are best developed by local community members, who work to alleviate the specific concerns of the community, build upon existing community assets, and move forward with the influence and momentum of the residents themselves.

Situational Crime Prevention: Specific Places and Times

Criminological Theories as Blueprints

Situational crime prevention is based on three major criminological theories. The first is rational choice theory, which posits that criminals decide to commit crimes after weighing the costs and benefits of such activities in a particular setting, at a particular time. The second is routine activities theory, which posits that crime occurs as the result

of a confluence of a motivated offender, a suitable target, and the absence of guardians to observe or stop crimes in progress. The third is crime pattern theory, which—similar to routine activities theory—posits that places can be crime generators, especially when they are hubs of activities for would-be offenders and victims. Places that provide criminal opportunities are known as *crime attractors*. And when these places have a dearth of protections or controls to prevent crimes, they are known as *crime enablers*.

Types of Situational Crime-Prevention Strategies

These three theories have become a roadmap for crime-prevention measures. The roadmap can be partitioned into four sets of strategies directed at the decision-making processes of motivated criminals in various circumstances. Strategy 1 makes offenders work harder to complete a criminal act. For example, target hardening protects property by placing it behind barriers. Stores with bars on the windows or solid steel retractable gates are more difficult to burglarize after business hours, compared with stores with glass windows or simple door locks. By applying techniques from the field of crime prevention through environmental design, homes and apartment buildings become safer by increasing prospect (i.e., the ability to clearly see an area through modifications that enhance open sight lines and illuminations), reducing refuge (i.e., providing few places for offenders to conceal themselves), and balancing escape (i.e., giving offenders fewer escape routes and potential victims more escape outlets).

Strategies 2 and 3 increase the risk and lower the rewards of crime, respectively. In Strategy 2, by increasing the risk of identification and apprehension through the placement of guardians (e.g., armed security guards) or surveillance technologies (e.g., closed-circuit televisions and cameras), offenders can be dissuaded from taking advantage of a criminal opportunity. In Strategy 3, the prospects for committing an offense are diminished when criminals are unable to clearly view a target and appraise its worth. Examples of reward reduction include jewelry stores that keep their most valuable items from public display, companies that design their mobile phones to disable if

stolen or lost, property identification programs (e.g., operation identification) that help police return stolen goods to victims, and police operations that disrupt illegal markets for selling (*fencing*) stolen goods.

Strategies 4 and 5 are more complicated than the others. The former involves manipulating situational cues, such as creating settings that promote civility and lessen conflicts. Also included in this category are efforts to neutralize peer pressures to engage in delinquent and criminal behaviors and to discourage the imitation of major crimes (copycatting) by hiding details regarding the mechanics of offenses (i.e., *modus operandi*) from the public. Strategy 5 reminds people in public settings about the parameters and expectations that govern acceptable and unacceptable behaviors in those areas and limits the ingestion of drugs and alcohol, which lower inhibitions to engage in violent and other antisocial behaviors.

Developmental Crime Prevention: Youth and Families

Poor Parenting and Risk Factors

The propensity to commit crimes can appear early in life. Crime-prevention programs that assume a developmental perspective are mostly family-, peer-, and school-based. Lackluster or ineffective parenting has been implicated in several theories of delinquent behavior and is the subject of a variety of correctives to teach or model better child-rearing techniques. For example, parents who are neglectful and detached from their children produce young people with low self-control and short time horizons, which contribute to criminal and similar high-risk behaviors (e.g., underage drinking and smoking). Other developmental avenues to crime prevention are administered in elementary schools in high-crime areas.

Other projects to prevent crime are directed toward altering the risk and protective factors in young people's lives, which increase or decrease the likelihood, respectively, that they will enter a trajectory toward delinquent and criminal behavior. For example, risk factors can consist of individual characteristics or traits (e.g., hyperactivity, impulsivity, and intellectual deficits), family dynamics (e.g., child abuse and neglect), and peer

pressures (e.g., inducements to join gangs and use drugs). Children reared in single-parent homes are at higher risk due to a lack of parental supervision and attachment. Similarly, young people who socialize with delinquent peers are also inclined to engage in delinquent behaviors. Protective factors are typically viewed as the opposite of risk factors. Hence, risk-focused crime-prevention interventions concentrate on reducing criminogenic forces and promoting protective influences in childhood and adolescence, thereby altering the pathway to delinquency and criminality.

Skills Building Among Youth

As noted, developmental crime-prevention programs are directed at the problem behaviors of both children and their parents. For example, the Promoting Alternative Thinking Strategies program is geared toward enhancing the decision-making and social skills of young children. Fostering brain development helps children control their behaviors and impulsivity and delay gratification more effectively. Improvements in social skills encourage children to solve interpersonal problems with words rather than physical aggression. A number of programs, including the Yale Child Welfare Program, the Incredible Years Program, and the Syracuse Family Development Program, have directed their attention toward low-income families and better outcomes for children through parenting education, home visits, and daycare services that lighten the burden of single parents. In general, these programs have reduced antisocial behavior and violence among the children in targeted families.

Institutional Crime Prevention: Offenders

Policing Tactics

The police, courts, and corrections (the formal system of justice) are all involved in different crime-prevention undertakings. Mostly reactive in the past, law enforcement agencies now commonly engage in several types of measures to stop crimes before they occur. Characterized by a wide array of tactics and technologies, these strategies first appeared during the community-policing era that began in the 1970s. Community policing is

also referred to as *problem-solving policing*, *public-order policing*, and *quality-of-life policing*. All of these terms underscore the police's role in crime prevention.

At the heart of community policing is the building of proactive problem-solving partnerships with neighborhood residents. The police spend less time in patrol cars and more time on foot in an effort to understand fully the neighborhood's most pressing needs and problems. Tackling small problems before they escalate to bigger problems, and eventually to criminal activities, is a principle crime-prevention component of community policing. For example, the dramatic downturn in crime in New York City began with initiatives that cracked down on subway toll jumpers (i.e., riders who avoided paying fares) and stopped improprieties and crimes on subway cars by placing police officers undercover as riders, creating a sense of the ubiquity of the police in that setting.

Based on the theory of *broken windows*, police attention to low-level public-order offenses (e.g., loitering, public drinking, panhandling, and noise pollution) fosters a social environment that is more hospitable to civil interactions and transactions and less amenable to disruptive and hostile behaviors that can often devolve into more serious criminal behaviors. Dampening down these social annoyances appears to be an effective preventive approach as environmental factors can have a powerful effect on people's behaviors in the public domain.

The use of computer-generated crime statistics to map crime is another strategy law enforcement has employed to control and prevent crime. Crime mapping displays patterns of different types of crimes that are geo-coded (i.e., identified by street addresses). These patterns give police clear graphic representations of *hot spots*, which are concentrations of criminal incidents on streets and in neighborhoods that require police attention. By saturating these hot spots with police officers on foot, on bikes, and in cars, a number of crimes can be prevented in the short term, particularly when patrol officers stop and frisk pedestrians for intelligence gathering and gun and drug confiscations. Displacement of crime from hot spots to adjacent areas can be problematic, resulting in little or no overall net reduction of crime in a community. Even more concerning is that aggressive policing

tactics can lead to citizens' complaints about police abuse, harassment, and racial profiling.

Courts and Corrections

Other criminal justice efforts to prevent crime are aimed at changing the traits of criminals and would-be criminals. The principal agents of change are the courts and correctional systems. Their efforts have been long-standing and have embodied the notions of rehabilitation and deterrence. Rehabilitation is concerned with changing the deep-seated nature of offenders by altering their fundamental views of themselves and others. Rehabilitation programs consist of a variety of interventions that aspire to alter the cognitions, feelings, and behaviors of sentenced offenders thereby altering their life courses from criminally inflected to law abiding. Examples include the adoption of religious orientations and beliefs, cognitive behavioral therapy, restorative justice programs, reintegrative shaming, and drug treatment.

Religious conversions and programming are common in prisons. The acceptance of common religious principles (e.g., love, forgiveness, faith in a higher power) is antithetical to criminal pursuits. Also modifying offenders' self-concept and worldviews, but with a non-spiritual bent, cognitive behavioral therapy challenges distorted and irrational thinking and destructive habits and replaces them with prosocial views and strivings. Community-based, and involving community members and crime victims, reintegrative shaming and restorative justice programs hold offenders accountable for their crimes but ensure that they are welcomed back into society. Drug treatment has proved to be a reliable means to prevent recidivism among convicted offenders. Addiction is a crime intensifier. Hence, the achievement of recovery and sobriety is correlated with a desistance from crime and the resumption of schooling and employment. Particularly effective are therapeutic community programs in jails and prisons. Relatedly, vocational training and educational programs in correctional settings also lower the rate of recidivism among formerly incarcerated individuals.

Deterrence applies to both offenders and would-be offenders and assumes that people are hedonistic (want to avoid the pain of punishment) and rational (understand the potential consequences of

criminal behaviors). Strict laws and harsh sentences are designed in part to dissuade convicted offenders from recommitting crimes and offenders-to-be from committing crimes in the first place. Called *specific deterrence*, the sentencing of an individual offender to serve a long prison sentence or pay a hefty fine is intended to ensure that the convicted person will be less likely to pursue future criminal opportunities. Called *general deterrence*, the generally known possibility of severe punishment for the commission of serious crimes is thought to keep in check the inclination to do so among members of the general public. The effectiveness of deterrence depends on the certainty, severity, and swiftness of punishment.

Final Thoughts

The implementation of crime-prevention policies aids in protecting the safety and well-being of residents, especially in poor neighborhoods where crime is more common and long-standing. Crime is costly to individuals, families, and communities, and the crime-control apparatus in the United States (i.e., the criminal justice system) costs the annual economy billions of dollars. Crime prevention must be multifarious. No one strategy will curtail the problem. The targets of anti-crime interventions include youth and their parents as well as members of the general public who are contemplating the commission of crimes and criminals who are considering reoffending. The targets can also be property, from cars to cell phones, as well as places, from subway stations to whole communities. The executors of crime-prevention policies, too, are varied. Teachers, neighborhood residents, police officers, and treatment providers can all contribute to the amelioration of crime and disorder in communities.

CRIMINAL ATTITUDES

Understanding criminal attitudes and criminal thinking patterns aids in understanding criminal and antisocial behavior. Theory, research, and clinical practice in criminology demonstrate that people in conflict with the law have different attitudes and thinking styles than people not in conflict with the law, and these attitudes and thoughts are connected to deviant conduct. Reliable and valid instruments that measure criminal attitudes and criminal thinking patterns allow various approaches to ameliorating treatments. This entry provides information about the concept of criminal attitudes and criminal thinking patterns as well as information related to the assessment and therapeutic options for them.

Concept of Criminal Attitudes and Criminal Thinking Patterns

Social sciences research has shown a link between cognition and behavior—in layperson terms, people act according to what and how they think. In criminology, it is recognized that criminal cognition (mental processes and functioning) is connected to antisocial and criminal conduct. At a conceptual level, the criminal cognition area consists of two distinct approaches—criminal attitudes and criminal thinking patterns. Criminal attitudes encompass values, beliefs, and rationalizations related to criminal and antisocial behavior. This concept reflects *what* a person thinks and has theoretical and empirical foundations in the broad attitude construct within social psychology. In essence, criminal attitudes are at the interface between criminology and social psychology. Criminal thinking patterns encompass cognitive processes in which specific erroneous styles of thinking make people prone to criminal and antisocial behavior. This concept reflects *how* a person thinks and is based on research by Samuel Yochelson and Stanton Samenow, who identified a criminal personality according to thinking styles of offenders. The differences between criminal attitudes and criminal thinking patterns are not merely conceptual but utilize distinct approaches to assessment and treatment. Currently, there is no theoretical, empirical, or practical evidence indicating that one approach is vastly superior to the other.

Role of Criminal Attitudes in Criminal Behavior

Theory, research, and clinical practice attest that offenders' cognitive content and processes are connected to their deviant behavior. At the theoretical level, a variety of disciplines have offered explanations as to why people involve themselves in antisocial actions, with criminal attitudes and criminal thinking patterns abundantly present in the majority of these theories. In social psychology, the theory of reasoned action is one of the dominant theories describing the relationship between attitudes and behavior and has been used to explain a variety of behavioral outcomes, including antisocial conduct. The essence of this theory is that attitudes (opinions about a person,

place, or event) and attitudinal influences (social factors) are connected to behavior by way of personal and environmental circumstances that create an *intention* to act. In criminological sociology, several traditional theories such as subcultural, control, anomie, and labeling offer explanations for criminality in which criminal attitudes are centrally linked to criminal behavior. In forensic psychology, the criminal attitude concept plays a prominent role in the general personality and social psychological perspective on criminal conduct, which is a comprehensive model of criminality that integrates multiple sources of influence leading to antisocial behavior.

Not only is there a theoretical connection between criminal attitudes and criminal thinking patterns and criminal behavior, but this union is supported by empirical research. The main source of this information emanates from reviews of the criminological literature using quantitative methods, also referred to as *meta-analytic literature reviews*. In this technique, a numerical relationship is calculated between the variable of interest and outcome, allowing for a rank-order comparison among variables of interest. Several meta-analytic type reviews in the criminological research have examined the relationship between various offender characteristics and criminal recidivism. These demonstrate a strong correlation between criminal attitudes and recidivism. More impressively, these findings are not unique to a specific offender group but rather are generic in that they are relevant to offenders of different ages (adults and juveniles), races, types of mental functioning (mental disorders), and offense types (general, violent, and sexual). Borne out of this research, criminal attitudes are generally considered to be one of the *big four* risk factors for criminality along with criminal history, peer influences, and personality variables.

In addition to theory and research, clinical practice also supports the connection between criminal attitudes and criminal thinking patterns and antisocial and criminal behavior. Field reports, published accounts, and anecdotal information from direct service personnel (e.g., probation/parole officers, psychologists, chaplains) confirm that offender's criminal attitudes and thinking styles are related to deviant behavior. Recent advances in the training and supervision of those working directly with offenders include such

models as the strategic training initiative in community supervision, which provides field personnel with specific knowledge and skills aimed at enhancing interactions with offenders and focusing on such topics as criminal attitudes.

Knowing that criminal attitudes and criminal thinking patterns are important ingredients in the commission of antisocial and criminal behavior gives rise to questions about the origins and stability of these cognitive factors. Understanding how criminal attitudes and criminal thinking patterns develop and endure aids in determining appropriate assessment and treatment options. Both the traditional sociological theory of differential association and psychological social learning theory converge to indicate that criminal behavior is learned from social sources, particularly other individuals and groups. Moreover, this learning includes the techniques or methods to commit a crime such as burglarizing a home, robbing someone, or acting violently, and the corresponding cognitive elements related to the motivations, attitudes, and rationalizations. A key step in the process of developing criminal attitudes and criminal thinking patterns is relevant exposure to an antisocial role model. By extension, the maintenance of criminal attitudes and criminal thinking patterns is dependent on the duration of time exposed to sources of antisocial influence—the longer and more dense the exposure (i.e., greater number of antisocial role models), the more ingrained and durable the criminal attitudes and criminal thinking patterns.

Assessment of Criminal Attitudes and Criminal Thinking Patterns

Determining the degree to which a person may possess criminal attitudes and criminal thinking patterns requires formal measurement directly with the client. There are two broad methods for assessing criminal attitudes and criminal thinking patterns—one clinical and the other psychometric. In the clinical method, the assessor engages the client in conversation and attends to any antisocial or criminal statements, phrases, and thought patterns. Based on the number, type, and frequency of such statements, phrases, or thought patterns, the assessor forms an opinion as to the level of criminal attitudes or criminal thinking patterns the client may have. The assessor often

provides general comments about the degree to which the client possesses criminal attitudes and criminal thinking patterns. The psychometric method of assessing criminal attitudes and criminal thinking patterns utilizes standardized questionnaires that have been validated using scientific methods. These comprise a set of questions related to a certain aspect of criminal attitudes and criminal thinking patterns, which are rated using an objective and standardized scoring system. The scores on the questionnaire are evaluated against a comparison group, or normative data, to determine the level of criminal attitudes and criminal thinking patterns, often presented in ranking terms (e.g., *low*, *medium*, and *high*). The clinical method can provide useful and direct information from clients but is susceptible to assessor bias. The psychometric method offers greater precision but is dependent on client honesty in answering questions. On balance, the psychometric test method is the preferred method for assessing criminal attitudes and criminal thinking patterns.

Several criminal attitudes and criminal thinking patterns-type questionnaires can be useful in research and direct practice applications. A dearth of commercially available criminal attitudes and criminal thinking patterns' test products, however, makes locating an instrument difficult. People interested in these types of instruments must do some groundwork such as searching research articles on the topic, consulting others who may be aware of test devices, or contacting test authors directly. The more popular criminal attitudes questionnaires are the Criminal Sentiments Scale–Modified and Pride in Delinquency, whereas the more popular criminal thinking patterns' questionnaires are Psychological Inventory of Criminal Thinking Styles, TCU Criminal Thinking Scales, Measure of Criminal Attitudes and Associates, Measure of Criminal Thinking Styles, and Criminogenic Thinking Profile. The selection of any one measure is dependent on the conceptual approach taken (criminal attitude vs. criminal thinking pattern), application (research vs. clinical practice), and group to be assessed (which relates to availability of relevant normative data).

Treatment of Criminal Attitudes

At the broadest level, the goal of intervention in forensic applications is to reduce or eliminate

deviant or criminal behavior. Modifying dysfunctional criminal attitudes and criminal thinking patterns as a therapeutic objective is a logical approach given the link between them and criminal conduct. Interventions of criminal attitudes and criminal thinking patterns, however, should be geared toward dysfunctional cognition at clinical levels as it is connected to deviant behavior. Assessment using some of the questionnaires previously mentioned is a key first step in selecting appropriate candidates for participation in criminal attitudes and criminal thinking patterns' interventions.

Criminal attitudes and criminal thinking patterns are mental actions, and therefore, treatment approaches are designed to alter those actions through cognitive restructuring methods. Two main treatment approaches—indirect and direct—have emerged in the area of criminal attitudes and criminal thinking patterns. Indirect approaches are those in which criminal attitudes and criminal thinking patterns are secondary to other clinical intentions such as general decision-making or criminological topics (e.g., substance abuse, anger management). The Cognitive Living Skills and Thinking for A Change programs are two examples of the indirect treatment approach. Direct approaches are those in which criminal attitudes and criminal thinking patterns are the primary focus of intervention. The earliest version of a direct criminal attitudes and criminal thinking patterns treatment was that of Don Andrews in the 1970s in which volunteers engaged offenders in discussions about various criminal topics and worked to alter these cognitions. More recently, the Criminal Attitude Program is a direct structured treatment program that helps offenders become more aware of and alter their criminal attitudes.

Future of Criminal Attitudes and Criminal Thinking Patterns

Theory, research, and practice indicate that criminal attitudes and criminal thinking patterns are a potent area for understanding antisocial and criminal behavior. The criminological literature shows that criminal attitudes and criminal thinking patterns can be adequately assessed, and various methods of treatment able to modify dysfunction were developed. Criminal cognition, then, involves understanding criminal attitudes and criminal

thinking patterns, selecting appropriate measurement instruments, and developing appropriate treatment methods based on these findings.

CRIMINAL CAREERS AND OFFENDING TRAJECTORIES

Not to be confused with the study of career criminals (e.g., individuals committing crimes as their primary source of income), the criminal career paradigm focuses on the longitudinal sequencing of an individual's offending pattern. This sequence is defined by different *parameters* detailing the beginning (e.g., age of onset), middle (e.g., changes in frequency, severity, and crime type), and end (e.g., termination) of an offender's criminal career. In the criminal career context, the term *trajectory* describes the frequency of offending between the start and end of an individual's criminal career, essentially capturing several of the aforementioned criminal

career parameters simultaneously. In effect, trajectories help describe the evolution of crime across the life course. Given that the majority of all crime is committed by a small percentage (5–10%) of all offenders, specific theoretical and policy attention has focused on the offending patterns of this group, sometimes referred to as *chronic offenders*. Trajectory research can help identify these chronic offenders and the risk factors (e.g., psychopathy, gang membership, substance use) that increase the likelihood that an individual will be associated with a chronic offending trajectory.

Measurement of trajectories requires a longitudinal research design involving self-reported or official measures of crime frequency at each age over a period of time that, ideally, covers multiple developmental stages (e.g., both adolescence and adulthood). This approach is different from recidivism-based (reoffending-based) approaches to studying offending, which involve shorter follow-up periods and capture a narrow aspect of an offender's criminal career. Whereas recidivism only differentiates between those who reoffend or do not reoffend, the trajectory approach better accounts for the heterogeneity of individual offending patterns by capturing differences in the nature of recidivism (e.g., some offenders recidivate once, others recidivate frequently over a long period of time, others recidivate frequently over a short period of time). Clearly, criminal justice system responses to chronic recidivists will be different from one-time recidivists, but recidivism studies cannot appropriately distinguish between the two types. This entry begins with an overview of the criminal career paradigm, followed by a description of research on offending trajectories, specific findings useful for practitioners, and directions for future research.

Origins and Description of the Criminal Career Paradigm

Interest in the longitudinal development of offending patterns emerged as early as the 1930s at the case-study level with classic works such as Clifford R. Shaw's *The Jack Roller*. The primary contribution of the 1986 National Academy of Sciences report, however, was to move beyond this case-study level of analysis in favor of more specific, measurable parameters of an offender's

criminal career. Initial research concerning offenders' criminal careers helped illustrate the positive correlation between past and future offending. For example, an earlier age of onset is associated with a criminal career that is longer in duration. A more frequent criminal career at one developmental stage (e.g., adolescence) decreases the likelihood of termination at another developmental stage (e.g., adulthood).

The criminal career paradigm has helped inspire or promote a wealth of longitudinal studies, including Sheldon and Eleanor Glueck's Unraveling Delinquency Study; Donald West and David Farrington's Cambridge Study in Delinquent Development; Marvin Wolfgang's analyses of the Philadelphia Birth Cohort; Terrie Moffitt's analyses of the Dunedin Multidisciplinary Health and Human Development Study; and three major studies initiated in 1986 by the U.S. Office of Juvenile Justice and Delinquency Prevention that took place in Rochester, Pittsburgh, and Denver. These studies recruited a cohort of children or adolescents of relatively similar age and followed participants throughout different periods of the life course to better understand the development of offending, including whether criminal careers differed according to gender, ethnicity, socioeconomic status, neighborhood environment, and different individual-level risk and protective factors.

Guided by the criminal career paradigm, the explication of the age-crime curve was one of the most important contributions from these studies. One of the few facts of criminology is the age distribution of crime. Typically referred to as the *age-crime curve*, the age distribution of crime shows that crime is most prevalent during mid-to-late adolescence but declines steadily and swiftly through adulthood. This finding is consistently produced across a variety of countries associated with different languages and cultures. Although this description of the age distribution of crime is widely supported, beginning in the 1980s, explanations for the age-crime curve were heavily debated between criminal career researchers and two eminent criminologists, Travis Hirschi and Michael Gottfredson. Hirschi and Gottfredson asserted that *all* offenders exhibit this age-crime curve pattern (i.e., a decline in the frequency of offending between adolescence and adulthood). On the other hand, criminal career researchers argued that the decline

in the age-crime curve was because *most* offenders completely terminated their involvement in offending during adulthood, but a small group of offenders maintained a high frequency of offending through adulthood. Imagine a sample of 100 offenders averaging three convictions per year between ages 12 and 17 years but only one conviction per year between ages 18 and 23 years. Hirschi and Gottfredson would argue that each of these 100 offenders slowed down in their frequency of offending. Criminal career researchers would argue that between 18 and 23, most offenders stopped committing crime, and a small proportion of offenders maintained a rate of offending between ages 18 and 23 that was similar to their rate of offending between ages 12 and 17.

Several of the aforementioned longitudinal studies helped support the criminal career perspective of the age-crime curve. For example, results from the Cambridge Study in Delinquent Development showed that the decline in crime during adulthood, as depicted by the age-crime curve, resulted from a large group of offenders terminating their involvement in crime at this age-stage. Among those who remained active offenders (i.e., committed at least one offense in adulthood), their frequency of offending between adolescence and adulthood remained stable. In effect, the age-crime curve pattern observed for the full sample was due to fewer participants in crime during adulthood rather than a decline in the frequency of offending in adulthood for all offenders. From a policy perspective, this was important as the findings indicated that all offenders will not simply age out of crime, and therefore, treatment and intervention strategies must be maintained over time. What this finding also implied was that different offending patterns characterize different offenders. Some researchers have attempted to identify, describe, and explain these different patterns using offending trajectories.

Trajectories: Description and Empirical Research

When different criminal career parameters are combined, beginning with onset and ending with termination, they comprise an individual's offending trajectory. Trajectories are consistent with person-oriented methodological approaches,

which involve examining and explaining within-individual change and stability over time. Monitoring within-individual change or stability is necessary to help understand, for example, whether a particular treatment or intervention strategy helped reduce an offender's frequency of offending. Although trajectories specific to one individual can be examined at the case-study level, a more common approach involves modeling the within-individual change or stability of offending trajectories that best accounts for the heterogeneity of different offending patterns within a sample. Based on a calculation of probabilities, individuals can be assigned to the aggregate trajectory that best resembles their individual offending trajectory. Importantly, classification is imperfect, and it should not be assumed that a particular aggregate trajectory perfectly describes the trajectory of all individuals within that trajectory.

Classic descriptions of different types of offending trajectories include Terrie Moffitt's dual taxonomy distinction between *adolescent-limited* and *life-course persistent* offenders. Adolescent-limited offenders follow a trajectory that starts in mid-adolescence and ends before adulthood, whereas life-course persistent offenders follow an offending trajectory that begins in early childhood and continues at a high rate through adulthood. The latter trajectory is believed to comprise only approximately 5% of all offenders. A critical issue for criminal career research involves moving beyond conceptual notions of trajectories, such as Moffitt's dual taxonomy, and toward an empirical understanding of the number and shape of trajectories that best describes a sample. There are a variety of statistical techniques and software packages designed to analyze offending trajectories. The statistical technique selected depends on the researcher's theoretical perspective concerning whether an individual's trajectory is best described as (a) the extent to which their trajectory varies from the *average* trajectory within a sample or (b) falling within a discrete category. The former is often referred to as *growth curve modeling* and is analyzed in statistical packages such as Mplus, whereas the latter is known as *semi-parametric group-based modeling* and is conducted through Proc TRAJ in SAS.

Irrespective of the statistical package used, trajectory studies have addressed core questions

arising from the criminal career paradigm and developmental and life-course criminology. For example, in 2015, Raymond Corrado and colleagues, using data from the Incarcerated Serious and Violent Young Offender Study in British Columbia, Canada, and, in 2012, Alex Piquero and colleagues, using data from the Cambridge Study in Delinquent Development, indicated that symptoms of psychopathy were associated with involvement in a trajectory characterized by a high level of offending across early adolescence and adulthood. From a policy standpoint, these and other trajectory studies illustrate the impact of adolescent risk factors on chronic offending through early and middle stages of adulthood, which recidivism-based studies are unable to address. Trajectory analyses are not only useful for examining risk factors predictive of a certain offending pattern; they can also be used to evaluate whether a particular treatment or intervention strategy is associated with a decline in offending.

Trajectory studies are also informative of whether specific types of offenders are associated with a particular offending trajectory. For example, research by Patrick Lussier and colleagues, using data from the Netherlands and Canada, indicated that juvenile sex offenders (a) typically do not go on to commit sexual offenses in adulthood, (b) are not involved in a greater number of sexual offenses in adulthood compared to juvenile nonsex offenders, and (c) are no more or less likely to be associated with a particular offending trajectory compared to juvenile nonsex offenders. The first two findings are contrary to many current criminal justice policies, such as the assumption that today's juvenile sex offender is tomorrow's adult sex offender. Using data on adult male sex offenders from Iowa, a 2010 study by Richard Tewksbury and William Jennings showed that the introduction of sex offender registration and notification policies did not reduce the frequency of sexual offending trajectories.

Limitations and Directions for Future Research

Limitations associated with accurately modeling offending trajectories include the issue of lengthy periods of incarceration for serious offenders.

The most serious offenders will be incarcerated for lengthy periods of time and will not have the opportunity to commit crimes that they otherwise might engage in when free in the community. Consequently, this serious offender will be associated with a nonserious or low-rate offending trajectory despite being characterized by risk factors associated with involvement in serious crimes. Incarceration time can be accounted for in trajectory modeling using statistical packages such as Proc TRAJ; however, several researchers have noted that even when accounting for exposure time, serious offenders are assigned to low-rate offending trajectories. Instead of focusing on number of arrests or convictions, future research should use length of time in custody over age to model offending trajectories. This strategy allows researchers to compare whether the most high-rate offenders are also most likely to spend the greatest amount of time in custody, or whether there is a subgroup of offenders involved in relatively few, but extremely serious, offenses, such as homicide and sexual assault. At a more conceptual level, debate remains whether trajectories are best described by variance around a normal distribution (i.e., one trajectory sufficiently describes all offenders) or by discrete categories approximating an unknown continuous distribution (i.e., the specification of multiple trajectories is needed to capture the heterogeneity of offending patterns).

Future research can move beyond trajectory analyses where frequency of general offending is the outcome of interest. Trajectory analyses can also be used to understand behavioral precursors to crime, such as childhood physical aggression trajectories. A less common, yet important, line of analysis for understanding the development of sexual offending is to examine sexual behavior trajectories during early childhood. As well, trajectory analyses do not require individual-level data. Another area for future research concerns *hot spots* for crime by examining the frequency over time of calls to police for service to different street segments.

CRIMINAL CHARGES, FEDERAL

Federal criminal charges are accusations filed in federal court, by a federal grand jury or federal prosecutor, asserting that a particular person or entity has violated a federal law, which carries penal sanctions. Federal criminal charges are relatively rare as the vast majority of crimes in the United States are prosecuted under state law, in state courts. Nevertheless, federal criminal charges have commanded sustained public and scholarly attention. This entry briefly surveys the history and evolution of federal criminal enforcement and highlights major debates in the field surrounding enforcement, sentencing, and the concept of *mens rea* (i.e., requisite mental state of the accused with regard to awareness of wrongdoing for the alleged criminal act).

History

In the early years of the U.S. republic, federal criminal offenses were limited in scope. They encompassed primarily offenses against the federal government, such as treason and bribery. With the rise of industrialization, urbanization, and interstate transportation in the 19th century, however, Congress increasingly used its legislative powers to criminalize public order as well as economic and social welfare offenses. Federal criminal lawmaking became even more expansive in the 20th century, aided by a series of New Deal-era Supreme Court decisions interpreting Congress's power to regulate interstate commerce broadly. This expansion was further spurred on in the latter quarter of the 20th century by rising crime rates and the perceived inadequacy of state and local enforcement to respond. By the dawn of the 21st century, estimates pegged the number of federal crimes at well over 4,000, though no official tally exists.

Yet while federal criminal law has grown exponentially, federal criminal enforcement remains relatively circumscribed. Congressional appropriations, administration priorities, and the relatively few federal courts, prosecutors, and law enforcement agents serve as functional limits on the scope and nature of federal criminal charges. As a result, federal criminal enforcement is focused primarily on drug trafficking, immigration-related crimes, financial frauds, crimes concerning firearms, and national security offenses.

Major Debates: Enforcement, Sentencing, and Mens Rea

In the late 20th and early 21st centuries, scholarly and public attention to federal criminal enforcement has revolved primarily around three primary areas: enforcement patterns, sentencing, and mens rea.

Enforcement Patterns

Since the 1980s, the federal government has increasingly focused on aiding state and local enforcement of so-called street crime, such as street-level drug sales, robberies, gun possession, and episodic violence. While some of that aid comes in the form of direct grants to state and

local law enforcement, it is also *in-kind*, meaning that federal law enforcement works closely with state and local law enforcement in investigating cases and increasingly brings more of these cases to federal court where, for a variety of reasons, conviction is more assured and punishment likely more severe. While some have applauded this expansion of federal criminal enforcement as an effective crime-fighting tool, others have criticized it as an encroachment on state and local authority, a misallocation of federal resources, and a source of unequal treatment of criminal defendants.

Sentencing

Until the 1980s, federal sentences were largely the result of discretionary decision-making by trial judges. That changed with the Sentencing Reform Act of 1984, which both established mandatory sentencing ranges (guidelines) to be set by a commission, and, for certain crimes, imposed mandatory minimum penalties. The guidelines and mandatory penalties have been widely credited for a shift in power away from judges and toward federal prosecutors as well as for a decline in federal trials and a rise in guilty pleas. While a number of states also began to use mandatory sentencing guidelines around this time, the federal guidelines became notorious for mandating higher penalties relative to many (though by no means all) state guidelines schemes.

The Supreme Court ruled the mandatory guidelines unconstitutional but upheld their constitutionality as an advisory scheme. Although no longer mandatory, the guidelines continue to heavily influence judicial sentencing decisions in most categories of crimes. Along with mandatory minimum penalties, they remain a focus of intense debate by scholars and policy makers.

Mens Rea

Mens rea (Latin for guilty mind) refers to a defendant's awareness of wrongdoing. Federal crimes do not have a uniform mens rea standard; the level of culpability required (e.g., whether a defendant must act *knowingly*, *intentionally*, or *willfully*) is defined by statute. Where a federal statute is silent on the matter, a court interprets the requisite mens rea. Courts, including the

Supreme Court, have interpreted some of these statutes as strict liability statutes—that is, requiring no guilty mind at all—and others as requiring a certain level of criminal knowledge or intent. Some have criticized this approach as haphazard and unclear, proposing that lawmakers should instead decree a default mens rea for all federal criminal statutes not otherwise specifying it. Others fear that such reforms will heighten the federal mens rea requirement, making it more difficult for prosecutors to prove guilt.

CRIMINAL COURTS

Criminal courts, and the criminal justice system, experienced a major transformation in the United States, beginning at the end of the 20th century and extending into the early 21st century. This transformation has expanded the role for the applied social sciences in contemporary criminal justice. This entry puts the changes in the field of criminal justice in historical context, places the role of applied social sciences within this context, and addresses two of the most critical challenges facing courts and the criminal justice system in the United States today: the incarceration of an unprecedented number of individuals in jails and prisons and the significant racial disparity among the incarcerated population in the United States.

The challenge of reducing the jail and prison populations and the implications of this for communities and for society as a whole are examined. Before exploring these challenges, it would be helpful to provide an overview of the types of criminal courts in the United States, the kinds of cases heard in these courts, and the major players in criminal courts and the criminal justice system.

Overview

Courts are among the most complex organizational structures in our society. This is particularly true regarding criminal courts, which not only operate on several jurisdictional and governmental levels but also carry a sense of gravity, given their adversarial nature and their considerable power to affect the lives of those who appear before them. In the United States, criminal courts are either under federal or state jurisdiction. Federal courts include the U.S. Supreme Court (the only court mentioned in the U.S. Constitution), U.S. Courts of Appeal, and U.S. Circuit Courts. Federal criminal cases, offenses that take place across state lines, such as major drug crimes, make up only a small percentage of criminal cases in the country. There are two other types of criminal courts related to federal courts: military courts and tribal courts. Military courts (Courts Martial) deal primarily with criminal offenses by military personnel that take place on U.S. military bases. Tribal courts have criminal jurisdiction over offenses committed on Native American lands by tribal members.

State courts include the State Supreme Court, State Appellate Courts, and State Trial Courts. State trial courts are the courts in which the overwhelming majority of criminal litigation takes place. Although state trial courts are often identified by the county in which they operate (e.g., the Los Angeles County Superior Court), they are, in essence, state courts governed by statutes of the state in which the crime took place and funded by either the state or the county or a combination of both levels of government. The two major types of criminal cases heard in state trial courts are misdemeanors (i.e., lower level criminal offenses punishable by up to 1 year in jail) and felonies (i.e., more serious criminal offences for which the

punishment ranges from 1 year in a state penitentiary to a sentence of death). State trial courts involve a myriad of players, the primary being the judge, the prosecutor (States' Attorney or District Attorney), and the defense attorney. Defense attorneys may be either private attorneys or public defenders (i.e., lawyers appointed by the court to defend individuals who are unable to afford counsel). On some occasions, defendants will choose to represent themselves in court proceedings. These defendants are called *pro se litigants*, and they are more common in civil cases than in criminal cases. Other key professionals critical to criminal case proceedings include sheriffs (also called *bailiffs*), clerks of the court, interpreters, court reporters, police officers, probation officers, and crime lab professionals.

Criminal Justice in the United States

To understand the status of criminal courts and the criminal justice system, it is necessary to review the broad outlines of its recent history. Like many social reforms, changes in criminal justice have been gradual and sporadic, but, in essence, the country has been moving away from a 40-year-old criminal justice model that incorporated harsh penalties for drug crimes, mass incarceration, and increased racial disparity, to a new model based on very different principles and priorities.

The old criminal justice model goes back over a half-century when, beginning in the 1960s and continuing through the 1990s, the country turned to what is often called *tough on crime* legislation. Although some saw this legislation as a reaction to public concern over the substantial rise in crime rates in the 1960s, there was also a political desire to equalize sentences, fit punishment to crime, and do away with the variability of sentencing across the country. Through a variety of statutory mechanisms, almost all states developed tougher criminal laws resulting in more severe penalties and, at the same time, the removal of judicial discretion in sentencing. Some of these laws, aimed at habitual offenders, incorporated a *multiplier effect* that greatly increased the length of sentences for return felons. As Americans increased their use of and addiction to drugs during this period, federal funding grew substantially to support local law enforcement in the *war on drugs*. Arrests for sale

and manufacture of illegal drugs and, most importantly, for possession of illegal drugs, escalated by significant proportions.

Two major phenomena emerged as a result of increased penalties and decreased judicial flexibility in sentencing: the incarceration of an unprecedented number of individuals in U.S. jails and prisons (i.e., *mass incarceration*) and an accompanying increase in racial disparity in the composition of incarcerated citizens in the country. By 2013, there were nearly 7 million U.S. citizens under the supervision of adult correctional systems and well over 2 million of them were in jails and prisons. Placing the concept of *mass incarceration* in perspective, the United States leads the world in the incarceration of its citizens in that; while Americans make up about 5% of the world's population, they account for nearly 25% of the world's prison population. At the end of the 20th century, the paradox in criminal justice was that major index crimes had been in a downward cycle for over 30 years while, at the same time, the jail and prison population were in an upward cycle.

In spite of similar patterns of illegal drug use across ethnic groups in the United States, people of color make up a disproportionate percentage of those arrested and incarcerated for drug crimes. In 2008, the Pew Center on the States reported that one in 15 African American men and one in 36 Latino men are behind bars compared to one in 106 White men. The starkness of this disparity, by race, led legal scholars and others, most vocally, Michelle Alexander, to the conclusion that there are structural elements of racism throughout the criminal justice system and that mass incarceration constitutes what can arguably be referred to as a racial *caste system* in the United States.

By the beginning of the 21st century, a number of social, cultural, and economic forces pushed the United States into rethinking the criminal courts and addressing serious criminal justice reform, primarily a reconciliation of the US\$50 billion that the United States spent annually across the criminal justice system with little public safety gain. Other drivers of the reform movement included the development of an evidence-based optimism about *what works* in criminal justice, a growing body of research in community corrections, a more enlightened public health view of addiction, an increase in public consciousness

regarding the ineffectiveness of and inequity in the justice system, mounting mistrust of police and prosecutors by minority communities, and public concern over the enormous burden and societal costs (personal, financial, and community) of incarcerating large numbers of individuals. As a result, a new criminal justice model emerged, one that moves away from mass incarceration as the primary solution to drug crimes. Diversions, and other alternatives to incarceration for nonviolent, drug-related crimes, are now viable options in many jurisdictions across the country, along with a heightened awareness, among policy makers and the public, of the challenge to society of returning large number of individuals, from jails and prisons, back to their communities.

Problem-solving courts (also known as *specialty* or *treatment courts*), which emerged in the 1990s, served as the lynchpin between old and new approaches in criminal justice. Problem-solving courts (e.g., drug courts, mental health courts, veteran's courts) are specialized court dockets that focus on problem-solving and treatment approaches rather than criminal sanctions. They combine intense judicial and court supervision with therapeutic services. Drug courts, in particular, have clearly demonstrated their effectiveness and paved the way for the justice system to develop new strategies aimed at reducing incarceration and recidivism. This new criminal justice model, although still in development, and with varying levels of implementation across the country, has the following salutary characteristics: It is data driven, focuses on outcomes (e.g., reduced recidivism) rather than outputs (e.g., convictions), is multidisciplinary in its approach, is science-friendly, engages a diversity of professions in the criminal justice process, and espouses a systemic viewpoint. That is, in addition to public safety, it looks more broadly at the impact of incarceration on minority communities and on society as a whole.

Interdisciplinary Collaboration

Often, the public view criminal justice as a single, integrated system. In reality, criminal justice is a very disparate system consisting of a number of autonomous players, each with their own authority and power base. Historically, the major players

operated in multiple, compartmentalized silos, with very little cooperation among themselves. The criminal court (adversarial in nature), prosecutor, public defender, private bar, police department, and the sheriff, although working in the same criminal justice arena, seldom shared information or collaborated with each other on systemic solutions to problems. In addition, due to the way in which much governmental public safety funding is structured (i.e., county government funds local jails and state government funds prisons), there were few incentives for close collaboration between different government entities. Today, courts are seen as only one piece of the criminal justice puzzle, and increasingly, interdisciplinary and multigovernmental approaches play a critical role in the field.

The Role of Applied Social Sciences

In a relatively new development, applied social sciences have come to play a more robust role in criminal justice practice. Applied social science fields such as criminology, psychology, social work, public health, sociology, economics, and urban planning are well suited for this interdisciplinary and collaborative work. In the new model, there is a closer relationship among the courts and major criminal justice agencies, with researchers and community treatment providers. Psychology has contributed to the criminal justice system through the development of innovative risk assessment instruments. These tools have become important at various points in the criminal justice cycle, including in bond court, where risk assessments are used to evaluate potential threat of flight and/or threat to the community; in the pretrial process, where clinical assessments are widely used to determine level of addiction and/or presence of serious mental illness; and in the posttrial disposition process, where clinical assessments are used by enhanced supervision programs in probation and parole.

Cognitive behavioral therapy (CBT), an innovation from the behavioral health-care field, has become an important component of the new criminal justice model. Research indicates that CBT is one of the most effective methods in targeting behavior change with the justice involved population. Although clinicians in the fields of

mental health and substance abuse have utilized CBT methods with clients in the past, more recently probation officers are learning and utilizing CBT interventions with probationers, a mark of interdisciplinary collaboration that could change the culture of traditional community corrections.

Social work, with a long history in interdisciplinary collaboration, has a key role to play in the criminal justice system. The contribution of social work lies in the broad orientation of the field, which incorporates micro- and macrowork; direct service and systemic public policy work; a commitment to disadvantaged, marginalized, and vulnerable groups; a focus on leveraging strengths (both at the client and system level); and a holistic emphasis on the importance of family and community in social change. On a policy level, this strength-based approach can be applied to entire jurisdictions. For example, a county must assess the court and treatment system for resources and gaps. It may have a good behavioral health system in place (strength) but no access for individuals without insurance (gap) or a strong substance abuse treatment system (strength) with little experience working with justice involved individuals (gap). Both system issues can be mitigated by first leveraging the strengths of current infrastructures and second employing interdisciplinary collaboration.

Community Reinvestment and Smart Decarceration

By the first decade of the 21st century, human rights advocates, faith leaders, the public, and elected officials of both major parties were in agreement that mass incarceration had failed. The mass incarceration model in the United States, while extremely expensive, has not demonstrated a significant reduction in crime or an increase in public safety. In response to this, a small number of states began to experiment with criminal justice reform through what came to be known as *justice reinvestment*. The term *justice reinvestment* is a trademarked term for data-driven methods to increase public safety, reduce criminal justice spending, and reinvest in strategies to decrease crime and reduce recidivism. The initial results of this experiment were encouraging and led to the appropriation, by Congress, through the 2010

Omnibus Consolidated Appropriations Act, of funding for the Justice Reinvestment Initiative (JRI). The JRI was launched through a public-private partnership involving public funds (Bureau of Justice Assistance), private funds (Pew Charitable Trusts), and governmental innovation (Council of State Governments). Under the JRI model, state and local policy makers, with the support of a technical assistance provider, conducted a comprehensive analysis of criminal justice data in a jurisdiction, identified drivers of corrections' populations and costs, and adopted policy changes designed to ensure public safety and support offender accountability. Bipartisan, interbranch justice reinvestment working groups are convened by each state to drive this process. The JRI model offered states a strategy to revise sentencing and corrections policies, reduce corrections costs, and increase public safety through a data-driven approach that ensures that policy making is based on a comprehensive analysis of criminal justice data and the latest research about what works to reduce crime.

It will be sometime before the results of the JRI projects are understood. While the initial round of JRI projects showed considerable promise and positive gains, subsequent research, conducted by The Sentencing Project, has shown mixed results. The research suggests that, in spite of initial gains, there is need for some caution. Missing from these early JRI projects were organized coalitions of community leaders, service providers, and grassroots leadership, underscoring the importance of genuine reinvestment in the communities most impacted by decades of failed criminal justice policies.

The Affordable Care Act, passed by the U.S. Congress in 2010, is another critical area for community investment. The Affordable Care Act has significant implications for the criminal justice involved population in the country. High concentrations of people with substance use and/or mental illness are involved in the justice system, the majority of which are low-income, uninsured males. The Affordable Care Act, primarily through Medicaid expansion and subsidy provisions for indigent males, creates unprecedented access to medical and behavioral health care for a population that in the past had, almost exclusively, been uninsured.

Finally, the new criminal justice paradigm addresses the significant challenge involved in returning large numbers of individuals, from jails and prisons to a small number of economically devastated communities. Neighborhoods with locally concentrated pockets of incarcerated individuals, sometimes referred to as *million dollar blocks*, because of the millions of dollars spent each year on incarcerated residents, have been identified in a number of large cities including New York City and Chicago. The concept of *million dollar blocks* highlights the need for community engagement, using scientific data to reframe government responses to crime and makes a strong case for genuine reinvestment and cost shifting.

The governor of the state of Illinois set a goal of reducing the state's 2015 prison population by 25% over a decade. For this to be accomplished, the prison population would need to be reduced by 12,000 individuals, many of whom would be released from Illinois prisons and returned home to seek reintegration into the community. The economic implications for this, as Matthew W. Epperson and Carrie Pettus-Davis point out, are intensified by the fact that over half of all prisoners were living in poverty the year before their arrest and that they reenter their communities with few resources, skills, and opportunities for employment. Epperson and Pettus-Davis advocate for what they call *smart decarceration*, stressing the complexity of reducing the jail and prison populations and the need for careful approaches to reentry, combined with community engagement and investment in community infrastructure. Smart decarceration is not just about reducing the number of individuals in jails and prisons but involves the strengthening of communities as a crime prevention strategy.

The future of the new criminal justice model remains to be seen. There is reason for optimism at this moment in time, as consensus among policy makers, scholars, and the general public is growing. In the meantime, much needs to be done in developing smarter sentencing policies; creating alternatives to incarceration; and solidifying the societal resolve toward a methodical reinvestment of financial, political, and social capital into local communities to ensure public safety and increase social well-being.

CRIMINAL CULPABILITY

Criminal culpability refers to the degree to which individuals are held legally responsible for their conduct and distinguishes between those who are wholly or partially blameworthy and those who are blameless. Criminal culpability is tied to the proportionality principle, which dictates that the harshness of a punishment be commensurate with the severity of the crime. Accordingly, punishment is doled out in consideration of the act the individual committed *and* the individual's mental state at the time of the act. For example, regarding the former, individuals who kill someone are punished more severely than are individuals convicted of driving under the influence. Both acts are illegal, but one act (killing) is inherently more harmful than the other (driving while intoxicated). Regarding the latter, individuals who kill someone in a car accident while driving under the influence are punished less severely than those who kill their victims by lying in wait. The harm suffered is the same—someone died. However, the law holds the second individual, who killed purposefully and with malice, to be more culpable than the first individual, who killed accidentally. This entry first reviews the legal facets of criminal culpability and then the role of mental health professionals in criminal culpability evaluations.

Legal Facets

Criminal offenses have two elements: the *actus reus*, literally translated from Latin as *guilty act*, and *mens rea* or *guilty mind*. To be held criminally culpable and found guilty of a crime, individuals must have committed *actus reus* *voluntarily*. In addition, with the exception of strict liability crimes (offenses punished regardless of the surrounding circumstances, such as speeding), to be found guilty, one must also evidence the *mens rea*. There are four types of *mens rea* or culpable mental states: (1) intentionally or purposefully, (2) knowingly, (3) recklessly, or (4) negligently.

Individuals act *intentionally* when they act with the conscious purpose of imposing a harm. For example, an individual commits first-degree murder when he purposefully lies in wait and kills another. An individual acts *knowingly* when he or

she does not intend to impose a harm but is aware that harm is a probable result of his or her act. For example, an individual may be guilty of homicide if he or she burns down an apartment building to collect on an insurance policy and a tenant dies in the fire. While the purpose of setting the fire was obtaining money, the perpetrator acted knowing that anyone inside the building was likely to die as a result.

Individuals act *recklessly* when they disregard the substantial risk of harm that could result from their actions. That disregard reflects an awareness that the risk exists and represents a significant departure from the way that law-abiding citizens would act in similar circumstances. For example, one who unintentionally breaks another's jaw after punching him may be guilty of aggravated assault because law-abiding citizens would refrain from such behavior due to the risk of serious injury involved. The case against the attacker is all the more compelling if he or she has training in boxing or martial arts and could even elevate his *mens rea* from recklessly to knowingly.

Individuals act *negligently* when they fail to perceive the harm that could stem from their actions. Such failure should reflect a substantial departure from the standard of care that reasonable people would observe in similar circumstances. For example, parents who do not know that leaving a baby in a car in summer can cause fatal heat stroke may be guilty of criminally negligent homicide if the baby dies in the car while the parents are in the grocery store. The parents acted negligently because, while their purpose was not to kill the baby and they did not realize the potential for the baby to die, they *should* have been aware of the risk.

Defenses

Criminal defendants can demonstrate they are not criminally culpable in two ways. First, defendants can utilize negation defenses that show the prosecution did not successfully prove all an offense's elements. Negation defenses apply to both the *actus reus* and *mens rea* elements of a crime. For example, defendants can contend that they were not in control of their actions and therefore not acting voluntarily (e.g., an offense committed while sleepwalking); this is referred to as the *automatism*

defense. Because an automatism defense challenges the actus reus element of a crime, it also applies to strict liability crimes. Similarly, defendants may argue that they did not have sufficient mens rea to be convicted. For example, an individual charged with homicide might argue that although he or she killed someone, he or she did not intend to kill. If the judge or jury agrees, he may instead be found guilty of manslaughter, a lesser offense that does not require a purposeful killing.

Second, defendants may assert affirmative defenses, indicating that they fulfilled a crime's elements but should not be considered blameworthy due to the circumstances surrounding the offense. Affirmative defenses come in two types: justifications and excuses. In *justification defenses*, defendants try to show that given the circumstances surrounding the crime, they did not act in an undesirable manner. For example, an individual who injures someone in self-defense is not deemed culpable for his or her actions because society has an interest in allowing one to defend herself when he or she is threatened with harm. Other examples of justification defenses include necessity, defense of others, defense of property, and consent.

In contrast, *excuse defenses* recognize that individuals have acted undesirably but suggest there are circumstances surrounding the offense—or characteristics about the defendants—that render them less culpable. For example, an individual who commits a robbery under threat of being killed still acts voluntarily and purposefully but is deemed less culpable than a defendant who commits robberies without the threat of death. Additional examples of excuse defenses include infancy, provocation, and entrapment.

The Insanity Defense

Still under the broader category of excuse defenses, the insanity defense is likely the most well-known attempt to negate criminal culpability. Defendants asserting the insanity defense may acknowledge that they committed harmful and wrongful acts but argue they should be exculpated because they were unable to appreciate the nature or wrongfulness of their actions at the time the crime was committed due to active symptoms of serious mental illness or cognitive disability. This

is referred to as the *M'Naughten Standard*, and—although not utilized in all jurisdictions—it is the most common standard in the United States. Under the M'Naughten Standard, a man might be found not guilty by reason of insanity (NGRI) of his wife's murder if she was fatally shot while he was firing at the hallucination of a monster breaking into their home. In that instance, he did not appreciate the nature of his act. In a different example, a woman might be found NGRI for her poisoning of terminally ill hospital patients because she believed to be acting on commands from God. In that instance, she knew she was poisoning and killing people, but she did not believe the act to be wrong.

Diminished Capacity Defense

Another type of defense often involving mental health evidence is the diminished capacity defense. Diminished capacity is similar to a negation defense, whereby one argues that the defendant did not satisfy the crime's requisite mens rea, but a diminished capacity defense relies on mental health evidence to support that claim. For example, in one tragic story, an intellectually disabled young man shot and killed his sister with what he had thought was a toy gun. In fact, it had been a real and loaded gun, only spray-painted bright gold. Although someone else might have appreciated the weight and feel to distinguish the weapon from a toy, evidence of his intellectual disability could persuade a jury he did not intentionally or knowingly shoot his sister; if the prosecution pursued charges with an intentional or knowing mens rea component, his intellectual disability could thus form the foundation of a diminished capacity defense.

Criminal Culpability and Forensic Mental Health Professionals (FMHPs)

Scholars have organized the roles of FMHPs into five broad categories, including basic scientist, applied scientist, policy evaluator, consultant, and forensic evaluator. A working knowledge of criminal culpability may be necessary for FMHPs in any one of these roles, whether it is coming to better understand the relationship between cognitive ability and mens rea, developing standardized

tools to measure mental state at the time of the offense, providing expert witness testimony as a teaching expert, lobbying legislative bodies, authoring amicus curiae (Latin for *friend of the court*) briefs, or providing advice to one side in a criminal trial about how best to utilize or manage mental health evidence. However, it is the forensic evaluators who conduct mental state evaluations who most often interact with the issue of criminal culpability.

Mental State at the Time of the Offense

A forensic evaluator asked to do an insanity or a diminished capacity evaluation is not being asked to opine on a defendant's criminal culpability; that is, a decision for the judge or jury. Rather, the evaluator is asked to provide an expert opinion on the defendant's mental state at the time of the offense. With that evidence in hand, the judge or jury may then decide whether the elements of an NGRI defense have been met or whether the defendant indeed had diminished capacity. Because of this nuance, these types of evaluations are often referred to more broadly as *mental state evaluations*.

Mental state evaluations are *past-focused*, specific to the time of the crime in question, and attempt to uncover how the defendant was functioning at that time. In this way, they contrast sharply with competence evaluations, which are *present-focused*, and attempt to measure whether a defendant possesses a rational and factual understanding of the charges and can effectively work with defense counsel.

One of the challenges faced by the broader forensic mental health community is the reconciliation of mental health diagnoses with legal constructs, and this is present in mental state evaluations and testimony as well. Case in point: Insanity is a legal construct, not a mental health diagnosis. Thus, after adoption of the insanity defense, there followed an evolution of cases in which, somewhat through trial and error, the courts decided which mental health conditions were sufficiently debilitating to satisfy the mental illness or cognitive disability prong of the insanity defense. Today in the United States, all jurisdictions require a *severe* disorder at the time of offense, with psychotic disorders constituting the majority of successful NGRI defenses. Other

disorders such as major depression, bipolar disorder, and post-traumatic stress disorder can also satisfy the mental illness prong, but they may require extra effort to show the condition as severe enough to make out the other prongs of the insanity defense (i.e., awareness of actions or awareness that actions were wrong).

In conducting a mental state at the time of the offense evaluation, many of the broader elements of forensic mental health assessment apply. Best practice guidelines recommend that referral questions should be clarified with the attorney or court, and it should be clear to all parties that the FMHP is an objective (i.e., not partisan) evaluator. Evaluators should engage in multimodal assessment, for example, by gathering data from clinical interview, through psychological testing or forensic assessment instruments specific to mental state, from collateral interviews with individuals who may have observed the accused's behavior around the time of the alleged offense, or through review of medicolegal records, either historical or around the time in question. Reports should reflect a synthesis of obtained information and the FMHP's impression, and testimony should reflect the content of the report.

There are also some elements of mental state evaluations that are unique and important for evaluators to be aware of. Most notably, interviewing the accused about his mentation and behavior at the time in question may uncover what amounts to incriminating evidence. While some procedural safeguards are in place—for example, the law may prevent use of the defendant's self-report by the prosecution to establish guilt—there are variations across jurisdictions. Failure to appreciate and be guided by the framework in place could end with the defendant worse off for having participated in the evaluation. Toward that end, and as always, it is important that FMHPs only participate in mental state evaluations if they are competent to do so, and if not they should seek supervision.

CRIMINAL JUSTICE CORRELATES OF PSYCHOPATHY

Psychopathy is typically defined as a *personality disorder* comprising traits associated with interpersonal, affective, and behavioral dysfunction, including superficial charm, manipulativeness, remorselessness, impulsivity, irresponsibility, and engagement in antisocial conduct. Of the psychological attributes that contribute to a heightened risk of criminal, aggressive, and violent behavior, psychopathy is one of the strongest and most widely researched predictor variables (i.e., an independent variable that is measured and used to predict the value of a dependent, or criterion variable, such as crime). Psychopathic traits predict higher rates of aggression, violence, and crime among civil psychiatric patients, criminal offenders, forensic inpatients, juvenile delinquents, and community members. Despite relatively small prevalence estimates for psychopathic offenders within the prison population (15–25%), these individuals tend to be responsible for a disproportionate amount of criminal activity. This entry provides an overview of the criminal justice correlates of psychopathy, noting that particular psychopathic traits tend to be more associated with the occurrence of various types of violent behavior while also emphasizing that the generalizability of these findings depends on multiple contextual factors.

Measuring Psychopathy

Psychopathy is used to inform a number of different types of criminal justice and legal proceedings

but is particularly common in decision-making processes concerning risk of future violence. Although not designed as a formal violence risk assessment instrument, the 20-item Psychopathy Checklist–Revised (PCL-R) is a widely researched rating scale of psychopathic traits that is frequently used in forensic evaluations, to the extent that it is required for some evaluation procedures in certain states. For example, in California, inmates sentenced to *life with parole* must be evaluated using the PCL-R for parole hearings, ostensibly to appraise the potential for general or violent recidivism if released. Frequently, the PCL-R has also been introduced to address preventive detention (e.g., civil commitment) of sexually violent or otherwise dangerous offenders and long-term community supervision determinations.

In terms of item content, the two-factor model of the PCL-R categorizes psychopathic traits into those reflecting interpersonal and affective deficits (Factor 1), such as deceitfulness and emotional detachment, and those reflecting social deviance (Factor 2), such as impulsivity, irresponsibility, and overt criminality. Each factor may further be subdivided to represent a four-subscale model reflecting Interpersonal, Affective, Lifestyle, and Antisocial aspects of the disorder. Ratings should be assigned by a trained examiner based on a review of collateral information (e.g., official records, informant data) and, preferably, a semi-structured life history interview. The instrument also has two commonly used derivatives, the Psychopathy Checklist: Screening Version and the Psychopathy Checklist: Youth Version.

There is some controversy concerning the extent to which the PCL-R comprehensively measures psychopathic personality traits. Specifically, recent criticisms argue that the PCL-R too narrowly focuses on criminal behaviors and other static indicators of psychopathy at the expense of core personality constructs historically associated with the disorder, including interpersonal dominance and emotional resiliency. Partially in response to the perceived limitations of the PCL-R, a number of alternative psychopathy assessment instruments have emerged and are in various stages of development, although they are not yet widely used in criminal justice settings. These include the

Comprehensive Assessment of Psychopathic Personality–Institutional Rating Scale and an assortment of self-report measures such as the Psychopathic Personality Inventory–Revised and the Triarchic Measure of Psychopathy. The Comprehensive Assessment of Psychopathic Personality–Institutional Rating Scale, in particular, diverges from the PCL-R by conceptualizing psychopathic personality traits as dynamic symptoms that are amenable to change over time.

General and Violent Recidivism and Institutional Misconduct

Given the substantial number of studies investigating psychopathic traits and criminal justice correlates, meta-analytic investigations have been especially advantageous in discerning the strength and variability of these associations. Meta-analysis provides a statistical means of combining and summarizing findings from independent studies to estimate the average effect size (e.g., correlation coefficient) and test whether study results may vary due to features of the samples, instruments, or research design. Collectively, extant research indicates that psychopathy, as measured predominantly by the PCL-R, has a small-to-moderate positive correlation with general and violent recidivism.

The individual components of psychopathy, however, are not equally predictive of recidivism. The same meta-analytic evidence demonstrates that an offender's risk of future crime and violence is primarily elevated by the impulsive, irresponsible, and socially deviant aspects of the PCL-R (Factor 2) rather than the interpersonal and affective deficits (Factor 1). For nonviolent recidivism, this pattern of association applies for both short-term and long-term follow-up periods, upward of 20 years postrelease. Moreover, the PCL-R total score does not significantly outperform Factor 2 alone in predicting risk of crime and violence, suggesting that Factor 1 traits make no additive contribution to predictive accuracy. This distinction has contributed to revisions in how psychopathy is incorporated into more comprehensive violence risk assessment instruments. For example, unlike prior editions, the revision to the Violence Risk Appraisal Guide only includes scores on the PCL-R subscale that primarily assesses prior criminal behavior, and the third version of the

Historical Clinical Risk Management-20 no longer requires use of the PCL-R or Psychopathy Checklist: Screening Version.

Typically, there is a weaker relation between psychopathic traits and sexual violence than for criminality and nonsexual violence, with Factor 2 features again appearing to be the most predictive aspect of the disorder. It may be the case, however, that psychopathy enhances the influence of other known risk factors for sexual violence. For example, sexual recidivism tends to be elevated among persons high in *both* sexual deviance and psychopathy compared with those without this combination of risk factors.

Taken together, there is a reasonably robust connection between psychopathy, as most often measured by the PCL-R, and a wide range of criminal justice outcomes. However, the average associations between psychopathic traits and antisocial behavior vary depending on the setting, population, and study design. To illustrate, psychopathic traits manifest greater predictive strength for samples comprising European and Canadian participants compared with samples of participants from the United States. Other variables that have strengthened the observed relationship between psychopathy and recidivism (i.e., moderated this effect) in prior meta-analyses include having a higher proportion of White participants in the sample; having a higher proportion of females in the sample; use of psychiatric inpatient versus nonpsychiatric inmate samples; and use of prospective studies, which involve following participants over time to measure future outcomes.

Finally, meta-analytic findings indicate a small-to-moderate association between psychopathic traits and disciplinary infractions incurred while institutionalized. Notably, this relation is weaker when the predicted misconduct is physically violent in nature, particularly among samples in the United States compared with those in other countries. This is in part due to the fact that serious violence is a relatively rare occurrence among incarcerated inmates in the United States, making it more difficult to predict with any precision. Consequently, making determinations of risk of serious violence in prisons is one instance in which psychopathic traits are not particularly informative, despite their broad relation with aggression.

This is an important consideration in death penalty cases in the United States, where capital sentencing in some jurisdictions is partially based on whether a defendant constitutes a future danger to others, specifically within a prison environment if a sentence of life in prison were to be imposed. In this context, PCL-R evidence has been argued to lack adequate relevance to warrant its introduction into these types of cases.

Instrumental and Reactive Violence

The nature of aggressive or violent behavior can be categorized, among other descriptions, as either instrumental or reactive. Instrumental aggression is generally characterized by premeditated and controlled behavior enacted in pursuit of an external goal, such as monetary gain or intimidation. In this type of predatory orientation, emotions are not the primary motivation for violence. Reactive aggression, however, does encapsulate an emotional reaction of, for example, fear or anger following perceived threat or provocation and an impulsive behavioral response. There is some evidence that the interpersonal features of psychopathy (e.g., deceitfulness, grandiosity) may be most strongly related to instrumental aggression, particularly when measured via informant report. In contrast, the lifestyle and antisocial features of psychopathy tend to have a relatively stronger association with reactive aggression, although the lifestyle subscale may be important in explaining instrumental violence as well. Knowledge concerning the relation between components of psychopathy and specific subtypes of aggression has accumulated more slowly than research on violent recidivism, as analyzing the function and motivation of violence requires relatively more rigorous study and may not be easily discerned from records. The most recent meta-analytic findings, however, suggest that the above patterns of association are dependent on the method of psychopathy measurement (e.g., effect sizes were smaller for examiner ratings vs. informant and self-report) and vary across gender, age, and ethnicity.

Juvenile Psychopathy and Recidivism

In general, youth offenders manifesting psychopathic traits are at a moderate risk of violent

recidivism, delinquency, and institutional misconduct during adolescence. As with the observed associations among adults, meta-analytic findings indicate that the impulsive and antisocial features of psychopathy more strongly relate to juvenile offending in comparison with the interpersonal and affective features. And, again, various characteristics of the study design, population, and context influence the magnitude of these overall trends. For example, stronger relations between youth psychopathic traits and criminal justice outcomes are reported when predictor and criterion variables are measured using an outside perspective, such as clinician ratings or informant report, than when using self-report. Notably, measures of juvenile psychopathy do have several limitations in predicting criminal justice outcomes, including poor predictive utility for sexual or long-term recidivism and weaker associations between psychopathic traits and general and violent offense outcomes among female and ethnic minority offenders.

Incremental Validity of Psychopathy

For both adults and juveniles, the significant associations observed between psychopathy and general and violent recidivism tend to remain even after taking into account the contribution of relevant covariates of psychopathy. Covariates are variables that occur with the predictor variable of interest and are possibly associated with the outcome under study, thus potentially suggesting an alternative explanation for any observed effect. For psychopathy, covariates include factors such as criminal history, substance abuse, demographic variables, and psychopathology. Some research, however, concludes that psychopathy-based measures do not demonstrate incremental validity beyond risk factors such as substance abuse and prior criminality and are in fact outperformed by formalized risk instruments developed specifically to predict criminal justice outcomes (e.g., Violence Risk Appraisal Guide, Historical Clinical Risk Management-20). Instruments developed specifically for juvenile risk assessment (e.g., Youth Level of Service/Case Management Inventory) not only perform comparably to psychopathy measures in predicting criminal justice outcomes broadly speaking but also tend to outperform measures focused on psychopathic traits in samples of females and ethnic minority youth.

Field Utility

Although findings from controlled research studies tend to support the utility of the PCL-R, a number of recent studies from field settings have raised serious questions about its reliability and predictive validity, especially in adversarial proceedings. Of particular concern is that inter-rater reliability in the field (e.g., sexually violent predator civil commitment trials) appears to be notably worse than what is reported in the instrument's technical manual. The poor agreement between two independent examiners rating the same defendant appears to be at least in part explained by adversarial allegiance (e.g., prosecution-retained experts provide higher scores than defense-retained experts), although expert witnesses who are retained by the same side on a case often disagree by an appreciable margin as well. Also of note, inter-rater reliability has been particularly poor for the interpersonal and affective traits associated with Factor 1, with close to half of the variance in scores being attributable to some form of error. Very poor reliability for Factor 1 traits is especially troubling given that numerous studies (e.g., mock jury simulations, juror surveys) suggest these traits are highly stigmatizing when ascribed to criminal defendants. For example, ratings on Factor 1 traits are strongly predictive of unfavorable release decision-making in California parole cases.

The low levels of inter-rater reliability in field studies raise questions as to whether the modest-to-moderate predictive validity for violence and recidivism reported in controlled research studies generalizes to the real-world contexts, given that reliability statistically constrains the validity of any instrument. Of note, extant field studies examining the validity of PCL-R scores in predicting criminal recidivism have demonstrated much weaker effects compared with findings from research contexts. This poorer performance in applied settings may be directly attributable to the negative influence of inadequate reliability on the validity of a measure.

CRIMINAL LIFESTYLE

The criminal lifestyle is a cognitive behavioral theory of crime comprising four models—two developmental models (control and moral modes),

a decision-making model, and a change model—each of which is discussed in this entry.

Factors Involved in Defining the Criminal Lifestyle

According to the criminal lifestyle theory, a criminal lifestyle is characterized by four behavioral styles: irresponsibility, self-indulgence, interpersonal intrusiveness, and social rule breaking. As such, involvement in a criminal lifestyle can be measured in terms of failing to meet social obligations (irresponsibility); striving for immediate gratification through drug use, gambling, and sexual promiscuity (self-indulgence); violating the personal space of others (interpersonal intrusiveness); and disregarding the rules, conventions, and laws of society (social rule breaking). Rather than being an all-or-nothing phenomenon, the criminal lifestyle is a matter of degree of involvement and commitment to crime. The Lifestyle Criminality Screening Form, scored using data from an offender's criminal file, can provide an estimate of a person's degree of involvement and commitment to crime.

Cognitive factors such as criminal thought content (what an offender thinks) and process (how an offender thinks), attributions (perceived causes of one's own or another's behavior), outcome expectancies (anticipated costs and benefits of engaging in a specific behavior), and efficacy expectancies (estimate of one's ability to successfully perform a specific behavior) also play a role in defining a criminal lifestyle. Criminal thought process can be further divided into proactive (planned, calculated, cold-blooded) and reactive (impulsive, spontaneous, emotional) processes. Proactive criminal thinking is characterized by blaming others or situations, having a sense of ownership and privilege, and exhibiting interpersonal control and overconfidence, whereas reactive criminal thinking is characterized by impulsive decision-making, lack of critical reasoning, and becoming easily sidetracked.

Developmental Models

According to the criminal lifestyle theory, the control and moral models of criminal lifestyle development are instrumental in the formation of a

criminal lifestyle. Although these two models are distinct, they overlap extensively. Behaviors (delinquency) and cognitions (thinking styles) shared by the two models serve as points of overlap or intersections between the control and moral models of lifestyle development. Each developmental model can be broken down into antecedent conditions, core constructs, principal mediators, and central components and processes.

Control Model

Antecedent Conditions

Disinhibition is a major antecedent to the core, central, and mediator variables found in the control model of criminal lifestyle development. As a temperament dimension, it represents a person's lack of restraint and poor ability to control his or her impulses, emotions, and behavior. Children who display high levels of disinhibition are at increased risk of future antisocial behavior. A second set of antecedent conditions are molecular social influences, related primarily to the family. Direct (e.g., weak parental supervision, lax discipline) and indirect (e.g., inadequate child–parent bond, lack of role models) parenting are particularly salient in promoting future antisocial behavior through the control model of criminal lifestyle development. A third set of antecedent conditions are molar social influences such as cultural, subcultural, and neighborhood factors. Neighborhood disorder and weak informal social control by neighbors may encourage future antisocial behavior according to the control model of criminal lifestyle development.

Core Construct

The control model's core construct is low self-control or behavioral impulsivity. This is sometimes referred to in the psychological literature as *externalizing behavior*. The antecedent conditions interface primarily, but not exclusively, with the core construct, in this case, low self-control. Hence, children functioning at the high end of the disinhibition continuum, whose parents are weak or inconsistent disciplinarians, and who live in a disordered neighborhood with minimal informal social control will tend to be low in self-control.

Primary Mediators

Criminal lifestyle theory uses statistical mediation to link constructs from different criminological theories for the purpose of theoretical integration. The principal mediator for the control model is reactive criminal thinking. Research indicates that reactive criminal thinking evolves from two primary sources: low self-control and delinquent behavior. Several other cognitive (hostile attribution biases) and affective (anger and frustration) mediators operate in the control model, including proactive criminal thinking. The impulsive and hyperemotional features of reactive criminal thinking may drive the control model, but proactive criminal thinking is also present. In fact, proactive criminal thinking is one of the constructs that bridges the gap between the control and moral models.

Central Components and Processes

Central components of the control model include general strain (loss of positive stimuli, as in divorce, or introduction of negative stimuli, as in peer rejection) and peer delinquency. These variables are connected to each other, as well as to the core construct of low self-control and delinquency, by the four primary mediators in the control model (i.e., reactive criminal thinking, hostile attribution biases, frustration, and anger). Two central processes in the control model of criminal lifestyle development are psychological inertia (past offending leading to future offending) and peer selection (delinquency leading to delinquent peer associations). In both cases, the processes are mediated by reactive criminal thinking.

Moral Model

Antecedent Conditions

The temperament dimension that serves as the antecedent to core and central variables in the moral model is fearlessness. Whereas disinhibition is characterized by lack of restraint, fearlessness entails weak autonomic response to punishment. Weak autonomic response to punishment impedes the individual's ability to learn from past mistakes and develop a functioning moral value system. The molecular social variable of parenting plays a

significant antecedent role in the moral model, just as it does in the control model. The parenting issues that serve as antecedents in the moral model, however, center on teaching the child to differentiate between right and wrong. Results from one study revealed that inductive parenting, in which rules for behavior were explained to the child and the reasoning behind the rules clarified, hindered the peer influence effect, a central process in the moral model. Subcultural attitudes toward crime and community tolerance of violence are culturally based antecedents to variable relationships in the moral model.

Core Construct

Callous-unemotional traits are the core construct in the moral model. Weak empathy, lack of remorse, and shallow affect are among the traits that contribute to the callous-unemotional pattern and that put a child at risk of future offending. A fearless temperament, parenting that fails to instill good moral judgment, and exposure to subcultural attitudes accepting of violence give rise to these callous-unemotional traits. These traits, in turn, interact with central components and processes from the moral model, which then enhance a person's odds of engaging in criminal behavior.

Primary Mediators

The principal mediator in the moral model is proactive criminal thinking. Rather than evolving from low self-control and delinquency, like reactive criminal thinking, proactive criminal thinking evolves from callous-unemotional traits and is learned through interaction with parents, siblings, and peers already involved in crime. Other variables known to mediate relationships in the moral model include outcome expectancies, efficacy expectancies, and reactive criminal thinking.

Central Components and Processes

Some of the same central components and processes from the control model can be found in the moral model. Delinquency and delinquent peer associations play as large a role in the moral model as they do in the control model, although they fit differently into each model. The peer

selection effect (delinquency leading to delinquent peers) predominates in the control model, whereas the peer influence effect (delinquent peers leading to delinquency) predominates in the moral model. Crime continuity (delinquency leading to delinquency) is present in both the models, but while it is mediated by reactive criminal thinking in the control model (psychological inertia), it is mediated by low self-efficacy or confidence to achieve a conventional lifestyle in the moral model (subjective disadvantage). Labeling plays a major role in the moral model and is instrumental in promoting the identity transformation process, which is mediated by deviant-reflected appraisals (how the individual believes he or she is viewed by others) and an evolving delinquency-based self-view.

Decision-Making Model

Whereas the control and moral models are designed to explain how a criminal lifestyle develops, the decision-making model shows how the criminal lifestyle influences the decision-making of individuals in a criminal lifestyle. The decision-making model of criminal lifestyle involvement comprises two belief systems, a hedonistic belief system and a moral belief system, both of which serve to influence, shape, and direct a person's everyday decisions.

Hedonistic Belief System

The hedonistic belief system is driven by perceptions of pain and pleasure. Criminal lifestyle theory assumes that people pursue options they believe will give them pleasure and avoid options they believe will give them pain. The individual relies on hedonistic expectancies to determine the anticipated likelihood of receiving pain or pleasure from a particular decision and then weighs the different options. The principal difference between rational choice theory and the lifestyle models of choice is the latter's emphasis on emotion. Hedonistic expectancies are attached to specific hedonistic emotions, which are the emotions aroused by the various options and the appraised likelihood of achieving these options. Common hedonistic emotions include anger, frustration, urgency, and excitement.

Accurate hedonistic expectancies and well-modulated hedonistic emotions lead to optimal

decision-making. Decision-making is less than optimal when hedonistic expectancies are inaccurate or unrealistic (e.g., expecting to secure a job that pays US\$100,000 a year right out of prison) and when hedonistic emotions are poorly modulated by the rational requirements of the decision-making process. Reactive criminal thinking, along with situational and developmental factors, plays a significant role in the criminal decision process by virtue of their ability to feed on hedonistic emotion and flood the decision-making apparatus with unmodulated and irrelevant (for the purposes of making a reasoned decision) emotion. Left unchecked, thinking styles such as cutoff (rapid elimination of common deterrents to crime) and cognitive indolence (lazy or short-cut thinking) impede reasoned decision-making by highlighting impulsive and short-sighted options.

Moral Belief System

Complementing the hedonistic belief system is the moral belief system. Rather than being rooted in pain and pleasure, the moral belief system is founded on principles of right and wrong; and instead of comprising past reward and punishment experiences and associations, the moral belief system comprises norms, standards, values, and morally relevant elements of a person's self- and worldviews. Moral expectancies are what individuals believe they will receive if they engage in a particular action. Moral emotions (e.g., guilt, remorse, shame, pride) are the affective experiences associated with these moral expectancies.

Whereas hedonistic emotions facilitate criminal decision-making by flooding the individual with irrelevant emotion, moral emotions facilitate criminal decision-making by removing moral constraints. Offenders neutralize moral emotions such as guilt and shame with proactive criminal thinking styles such as mollification and entitlement. Hence, proactive criminal thinking, in combination with sundry situational and developmental factors, facilitates criminal decision-making by removing the moral impediments that ordinarily block criminal action. Right and wrong are replaced by expediency in achieving a criminal goal or objective.

Outcome Feedback Loop

The hedonistic and moral belief systems are continually being modified with feedback from the outcomes of a person's decisions. Success in crime—and research indicates that offenders get away with over 90% of their crimes, at least during the early stages of a criminal lifestyle—alters both hedonistic and moral expectations. Failure in crime and success and failure in a conventional lifestyle further alter these expectations and with them the strength of certain hedonistic and moral emotions.

Change Model

The change model of criminal lifestyle commitment comprises three phases: preparation, action, and maintenance.

Preparation Phase

During the preparation phase, the individual prepares to desist from crime. Shifting one's commitment from a criminal lifestyle to change is the key to successfully negotiating this phase of the change process. Although most individuals who desist from crime do so without treatment, a process known as *unassisted change* or *natural recovery*, desistance from crime is viewed to be based largely on interpersonal relationships, whether that be with a counselor, a probation officer, or a family member. Results from a 2016 study published in *Personality and Individual Differences*, in fact, indicate that a strong working alliance with a therapist or probation officer can be hindered by proactive (callous-unemotional traits, self-centeredness) or reactive (impulsivity, hostility) criminal thinking. Therefore, both should be targeted in any intervention.

Action Phase

The action phase of the change process is directed at making specific changes in thinking and behavior. A cognitive-behavioral approach is recommended, although again, it is important that both proactive and reactive criminal thinking be addressed. Traditional treatment programs for offenders typically focus on cognitive-behavioral (e.g., problem-solving, anger management) skill building; while this can be effective, it only addresses the reactive part of the problem. The

proactive part of the problem can be addressed through value clarification, moral retaining, and perspective-taking interventions.

Follow-Up Phase

Once change has been initiated, it must be maintained. Proactive and reactive criminal thinking not only tie the phases of change together, they also connect the four models of criminal lifestyle theory. During the maintenance phase, the focus is on the proactive-related issue of creating a noncriminal identity and on the reactive-related issue of overcoming fatalism with empowerment derived through successful application of prosocial skills.

CRIMINAL ORGANIZATIONS AND NETWORKS

One way to think about criminal organizations is as social networks. A network is a set of discrete entities connected to one another. By using a

network-based approach to analyze the links among criminals, scholars have developed a better appreciation for the relationships that underpin organized crime. Research has begun to capitalize on this progress and suggests specific strategies by which law enforcement can understand, prevent, disrupt, and demolish criminal organizations based on the nature of the underlying networks.

Criminal Organizations as Networks

Criminal organizations operate as businesses with the objective to make money. However, unlike people or firms engaged in legal activities, perpetrators of illegal activities cannot access the many institutions that lower the costs of doing business and allow engagement in normal economic transactions. Formal institutions such as the legal system or marketplaces in which goods and services are bought and sold are central to profitability through the efficient enforcement of contracts and transmission of information these institutions allow. Those engaged in criminal activities have limited access to formal institutions and are therefore more likely to rely on comparatively costly interpersonal channels of communication and enforcement of agreements.

Unlike market institutions in which a person can participate with minimal revelation of his or her characteristics—a corner store hardly cares about one's personal qualities beyond the ability to pay for one's vegetables or soda pop—illegal transactions require greater knowledge about the participants on both sides of the transaction as well as trust between them. The seller and buyer in an illegal transaction need to worry about the quality and nature of the good or service being bought or sold and the likelihood that enforcement of the informal *contract* between the parties is possible at sufficiently low cost. Contrast, for example, a legal transaction at the pharmacy for aspirin using a credit card versus an illegal purchase of cocaine from a street dealer using cash. Not only are the participants forgoing the use of credit or other convenient means of payment that would leave a trail, but they are also subject to the added anxiety about whether one of them might be a police agent.

A shorthand characterization of the key difference between the required information about

participants in legal and illegal activities is to say that markets allow for transactions among anonymous individuals who need only to know the going price to make a purchase, whereas illegal markets require intricate trust and knowledge among the participants. Social networks intrinsically emphasize the individual actors and their relationships to one another and are consequently a valuable way to model and study relationships among criminals.

What Constitutes a Network?

A social network is defined as a set of individuals and the connections among them. Each individual may be thought of as a *node* from whom connections (*links*) spring. The connections can be unidirectional or bidirectional and can have an intensity that is potentially different in each direction. There are two basic approaches to model the structure of connections in a network. The first approach assumes that the connections are preexisting or determined outside the scope of the analysis. Prime examples are networks based on kinship that are extensively used in anthropology and sociology. In the context of crime, an example would be crime families. The second approach assumes that networks form as a consequence of purposeful behavioral choices. The participants in a network are better-off through their group behavior than as stand-alone criminals. While the *cosa nostra* (mafia) may focus on family ties, there are numerous criminal organizations ranging from outlaw motorcycle gangs to street gangs to the yakuza that display no such family associations.

Network Persistence

Typically, criminal networks display persistence—the particular structure of links and nodes remains relatively stable over the period of time relevant for analysis. The persistence of criminal networks allows them to create and preserve valuable information and trust among their members. In some cases, this may be a consequence of familial ties or common interests, but more generally, the persistence arises as the outcome of adaptive behavior to a stable environment. Network analysis assumes a set of external or environmental conditions that can be viewed as inputs into the behavior of the

criminals pursuing their interests. The underlying stability of the players and links that form the network is an important result of this behavioral process.

Examples of Criminal Networks

Criminal networks have been used as a tool for analyzing a wide variety of applications. Human trafficking; illicit substance distribution including tobacco, alcohol, cocaine, heroin, and other drugs; the manufacture and provision of illegal goods; delinquency; and other illegal activities have all been studied through the lens of network theory. These studies have emphasized the ways in which criminals are connected to each other and the specific configurations of connections that appear to lead to particular benefit to the network. The studies frequently pinpoint individuals who are centrally located or are key players in the network's structure. The ambit of research on criminal organizations also naturally extends to some aspects of terrorism. The structure of at least some terrorist organizations has many of the characteristics of a network, albeit often more ideologically motivated than traditional criminal networks.

Some dimensions of observed networks are easily characterized. For example, a study of heroin dealing finds that the *star* structure in which each dealer is connected to a number of clients fits the data well. Suppliers, however, are also connected to each other as well as to their dealers. The overall shape of the organization that puts heroin on the street is hence not well mapped to a traditional top-down hierarchical structure but is better described by a network. Numerous other criminal networks have been observed, but part of the role of recent research is to identify what network structures researchers should *expect* to observe. Thus, the role of network analysis is not only descriptive but also prescriptive, as it may suggest network characteristics useful for policy.

The Network Approach to Organized Crime

Network theory studies the consequences of the links among participants. These links are simultaneously a source of benefit and a source of risk or other costs. Compared to acting individually, the benefit from being connected to other criminals

arises from an underlying activity that allows the network members to obtain a greater gain by participating in the network. By being connected through people who are also connected, an individual's benefit is drawn from the entire network not simply from one's direct connections. Similarly, the costs of being part of a network may be also related to the extent of one's connections: There is a risk of discovery or capture by law enforcement as well as costs of establishing and maintaining links with other criminals. The interplay of the costs and benefits both determine and circumscribe the scope and structure of links in the network.

Early analysis of criminal organizations tended to use organizational theory to describe criminal groups. Such theories emphasize relationships among patrons and clients in the context of a structured crime *business*. The network-based approach places the emphasis elsewhere. For example, some crime-related network theories highlight the importance of lacunae among subgroups of participants who are linked by a small number of agents who act as brokers of information and providers of services between more tightly organized groups. These brokers or *key players* are seen as important to the overall criminal enterprise because they raise the income generated by the entire network.

Others argue for a functional rather than an individual-based approach to characterizing criminal networks. For example, a study of human trafficking has looked at the tasks associated with recruitment, transportation, and exploitation. Certain fundamental roles have to be filled within the trafficking network, but there is no need for a single structured organization or specific individuals. Individual actors can form temporary connections with a variety of other players, but the roles and the links among them remain the same.

The network approach is distinct from alternative approaches that emphasize associations based on the aggregation of individuals. These *peer effect* approaches assert that average or aggregated characteristics or actions by members of the group affect individual behavior. Typically, all group members are treated equally, without regard to the precise structure of social connections among them. In contrast, network theory generates its own set of concepts related to the

multiplicity of possible configurations of links among the members. Ideas such as network *density*, characterizing the frequency of links among players; network *centrality* of particular players (how many paths among members pass through specific nodes); and *distance* (the number of links separating one player from another) play important roles. For example, greater delinquency from peer association has been found to increase with network density. Consequently, the specific structure of a crime network is relevant for characterizing criminal behavior beyond simple peer effects. Location in the network—which can be quantified using the measures of density, centrality, and the number of links associated with a node—can provide a better predictor of delinquent involvement than simply knowing the aggregate attitudes of a criminal's peers.

Optimal Crime Networks

The network theories characterizing criminal organizations discussed thus far are traditional and descriptive. They are characterized by an extant organization made up of interpersonal links about which a description is constructed of centrality, connectedness, distance, among others. More recent functional approaches point to the origin of the networks themselves. Networks arise as a consequence of underlying intentional and strategic behavior by their participants. For example, by using an assumption common to economists—that individuals maximize their well-being (or utility)—the costs and benefits from criminal activity arise from the underlying parameters of individual payoffs and the economic and criminal environment. This in turn determines the observed or predicted *structure* of the network, in addition to the activities of its members. Thus, the characterizations of centrality, density, key players, and the like can be viewed as *outcomes* of rational choice instead of mere statistical network descriptors.

Sharing this common assumption, one strand of research takes the network structure as determined prior to the analysis (but possibly unknown) and analyzes the outcomes achieved in a strategic equilibrium across different network structures. By strategic, it is meant that players are aware of or make behavioral assumptions about the actions

of other players in the network. For a particular network, the incentives of individuals to engage in crime depend on the structure of links among them. Each criminal chooses a level of *effort* (criminal activity) assuming, for example, that the effort levels of all other members in the network are outside of his or her control. The chosen effort level determines the criminal's net payoffs: the rewards less costs. The latter might include being captured and penalized if caught, the psychic costs of being a criminal, or out-of-pocket costs.

The individual criminal efforts and the aggregate crime level are determined in a Nash equilibrium. This is a game theory concept in which each player treats the strategies or actions of the other players as fixed and chooses his or her best response to them. In the equilibrium outcome, no player can gain by unilaterally changing his or her own strategy. This framework allows a characterization of individual activity in a crime network as a function of the Bonacich centrality measure, according to which each network member is assigned a weighted score based on his or her direct and indirect links to others in the network. This in turn allows identification of the *key player* in a crime organization—the individual whose removal would reduce criminal activity by the largest amount. A policy implication is that law enforcement policy that directly targets such individuals would be more successful than a policy targeting those who simply do the most crime or a policy targeting criminals in an indiscriminate (random) way.

A second approach to modeling crime networks takes the network itself as an object of choice. Network formation is viewed as the result of a strategic optimization process. Links are formed at the discretion of the individuals involved, and game theory is used to predict what *stable* networks emerge. This approach retains the idea of maximizing behavior by the participants and assumes Nash equilibrium, but unlike efforts in which the network is predetermined and outside the scope of the analysis, the network itself is also the outcome of optimization. The latter can either take a decentralized form—the network is the end result of the actions of individuals forming links strategically but bilaterally—or a centralized form by assuming, for example, a criminal *godfather* who controls the network and shapes it in a way

to maximize profits. Terrorist activity can also fit into this framework. Finally, the optimal network structure could also emerge as the result of natural selection through the process of competition (e.g., gang wars) with other criminal organizations.

Implications for Law Enforcement Policy

Network theory provides a useful framework for understanding both the visible and hidden links in a criminal organization. If the socioeconomic or statistical model of a criminal network is sufficiently precise and the appropriate data exist, then a prediction about the structure of the criminal network—who is linked to whom—provides valuable guidance to law enforcement about where to look for what is missing among the observed connections.

Law enforcement is particularly interested in what strategies would do the greatest harm to a criminal organization. The network approach offers clear prescriptions about this. Given limited resources, identifying the key player, the person whose removal will cause the greatest harm to the network in terms of criminal activity, is important. Measures of network centrality are shown to provide a useful guide to identifying the appropriate target. Researchers have extended the same logic to target optimal groups of key players. Law enforcement and antiterrorism efforts also explore issues such as destabilizing crime or terrorist networks and preventing them from reforming.

Considering both the network structure and the activities of its members as outcomes of optimizing behavior provides additional ways to identify and solve the problems facing law enforcement. For example, if criminals understand and expect that enforcement would target the key player, then the network that forms may not be the same network that would arise in the absence of such law enforcement policy. Criminals may choose organizational structures that are the most robust to the particular enforcement environment and strategy. Failing to understand that criminal networks may anticipate the crime fighting policy environment can thwart crime-combating efforts. What may appear to be the best anticrime or counterterrorism strategy planned for a network structure that is observed before the anticrime strategy is adopted, may be substantially different once the

criminal organization reacts to the policing strategy. This observation is relevant to both criminal and terrorist organizations.

Empirical Research

Empirical studies have spanned a wide variety of criminal networks related to the market for art and antiquities, pornography, cybercrime, among many others. Since it is already digitized, to the extent that data collection can be automated, identifying large networks in the Internet environment is relatively easy—at least in contrast to gathering data about street-level networks. This has led to a series of studies on Internet crime including phishing, banking fraud, theft of account information, propagation of malware, computer viruses, among others.

Although as of 2018 it still remains relatively rare, some police departments and other law enforcement agencies are using network models to help identify the key players, the most active players, or other analytically significant players to watch or arrest. Describing crime networks in visually suggestive ways has been an important technological advance since it allows investigators to systematize their knowledge and transmit it efficiently. Beyond graphics, continued development of network analytics—computing centrality, density, and key players—and borrowing from graph theory in mathematics provides a richer understanding of the network characteristics to help evaluate and guide policy.

There is substantial complexity in using historical data to predict the outcome of an intervention by law enforcement because large and sophisticated networks of criminals or terrorists may be well aware of the actions of the authorities. If the crime network is taken as predetermined, then any action by the authorities would be a surprise to network participants. Finding the key player, for example, would locate the person whose removal would do the most damage to the preexisting network. Many networks may fall prey to such an analysis. However, if the network itself is an object of choice by the organization, then the criminals can use their knowledge of police strategy to adjust the network structure as a function of the expected policy. Thus, the historical characterization of the network may no longer be relevant if

the police strategy is known in advance. A more sophisticated behavioral model that accounts for the criminals' expected reaction to the new law enforcement policy will be necessary to ensure success. Failing to do so is inherently flawed and can have unintended consequences.

Although applying network theory to crime has progressed over the years, as a systematic crime fighting tool, it still has a way to go. Many current applications are primarily based on descriptions of extant networks. Progress will come with applications that are increasingly able to model the underlying costs and benefits to the participants in criminal organizations and are consequently able to anticipate and take into account their responses to enforcement policy and environmental changes.

CRIMINAL PROFILING

Criminal profiling represents a technique wherein the behavioral features apparent in a crime or series of crimes are assessed for the purpose of

formulating a template of descriptive features concerning the likely perpetrator of the crime or crimes. The technique is typically used to assist police personnel who are investigating crimes, often of an aberrant violent nature, which are not readily solved via standard investigative procedures. The information contained in a criminal profile typically includes demographic features such as the offender's age, gender, level of education, marital status, vocation, and personal interest but can also extend to highly specialized forms of information such as the area wherein the offender may reside or analysis as to whether multiple crimes were perpetrated by the same offender. Equipped with the information contained in a criminal profile, police investigators can better coordinate their investigations concerning existing suspects and use the information to develop further lines of inquiry that may potentially lead to the identification of new suspects. Importantly, criminal profiles are not a panacea for solving an intractable crime but merely represent another form of investigative tool, akin to fingerprints, for police agencies to use.

This entry begins by reviewing the history and theories of criminal profiling. Next, the entry addresses the issues of validity and utility of such profiling. Last, the entry discusses controversies and concern regarding criminal profiling as evidence in judicial proceedings.

The History and Theories of Criminal Profiling

Contrary to popular culture depictions, the concept of criminal profiling is, in fact, very old and reflects a long-standing fascination that human societies have held in attempting to understand the reasons individuals perpetrate crimes. Early fictional conceptions of criminal profiling appear in the novels of Sir Arthur Conan Doyle and his consummate detective, Sherlock Holmes, in 1886. However, real-world manifestations of criminal profiling date back to 1878 and the seminal works of Cesare Lombroso, the founding figure of modern criminology. Early examples of the use of criminal profiles in police investigations can also be traced to historically infamous cases such as the 1888 Whitechapel (*Jack the Ripper*) murders or the kidnapping and murder of Charles

Lindbergh's 20-month-old son, Charles Lindbergh Jr., in 1932.

Field and contemporary approaches to criminal profiling are analogous to the topic of personality theory and the construct referred to as the *mind*. However, precisely how the human mind functions is the source of considerable scholarly discourse and debate with the formulation of numerous differing theoretical paradigms such as psychodynamic, behavioral, and cognitive schools of thought. The field of criminal profiling is similar in its analysis of behaviors exhibited in crimes for the purpose of deriving an impression of the likely perpetrators. However, akin to the field of personality theory, the methodological basis as to how this analysis is optimally achieved is the source of discourse with a variety of differing theoretical approaches. Also akin to the field of personality theory, each of these rivaling approaches to criminal profiling features their own inherent merits and limitations, and there is no definitive approach that can claim to be the optimal method of profiling crimes.

Some of the conceptual features to these differing approaches relate to their disciplinary origins and vocational focus. Criminal profiling by the U.S. Federal Bureau of Investigation, for example, is a heavily pragmatic orientation in its endeavor to develop accessible methods and information that can be readily accessed and utilized by law enforcement agencies. In contrast, academic researchers endeavor to develop replicable theories more aligned with the traditional conventions of the scientific method. Further differences in the field also relate to specialized modes of analysis encompassed under the broader rubric of criminal profiling. One such example is the mapping and analysis of crime locations, which are used as the basis for gauging the likely area where an offender may reside. Unlike the broader range of research in the field that largely stems from mainstream criminology and clinical forensic psychology, these analyses derive from the disciplinary fields of geography and environmental psychology.

Differences in theoretical perspective, however, relate to the degree of commonality (in terms of characteristics) that offenders who commit similar forms of crime may share. In this context, the theoretical differences in opinion are largely split into

two perspectives. One view is that there are few or no robust commonalities to be found among offenders. The alternative is that some commonalities exist, but they are largely sourced in psychopathological factors that certain offenders commonly share. Accordingly, it is these psychopathologies that play a role in particular forms of crime that certain offenders typically perpetrate as well as the characteristics they commonly share.

The Validity and Utility of Criminal Profiling

Despite the wide renown which surrounds the topic of criminal profiling, there is a shortage of scientifically grounded research that attests to its validity. This deficit is largely attributable to a variety of methodological difficulties in objectively measuring the accuracy (ergo, the validity) of criminal profiling. For example, the largest source of readily available material that attempts to demonstrate the validity of criminal profiling comes from a variety of anecdotal accounts, such as case examples, concerning the use of the technique. While this type of material provides qualitatively rich demonstrations of the investigative applications of criminal profiling, these do not represent impartial empirical measurements and therefore cannot be warranted.

Likewise, the seemingly straightforward compilation and post hoc assessment of past cases using criminal profiling by police investigators is similarly unreliable. In this circumstance, any measurements concerning the accuracy of criminal profiles are compromised by the inability to reliably discount (and thus control for) any particular attributes inherent to the differing cases, which may account for the outcomes. Consequently, evidence supporting criminal profiles obtained via this methodology fails to demonstrate that any observed proficiency is unique to the circumstances of each case.

While there is a shortage of research attesting to the validity of criminal profiling, emerging data meant to rectify this consist of quasi-experimental designs using various groups of participants undertaking profiling exercises based on previously solved actual cases. The results of these exercises, then, in terms of their accuracy, can be objectively measured. The overall outcome of this research has been scientifically robust evidence

demonstrating that suitably qualified individuals (*profilers*) are capable of proficiently predicting the characteristics of unknown offenders in a host of differing crime modalities. While this research has shown great promise, however, it has thus far only been able to demonstrate validity in a generic capacity.

Akin to the issue of validity, a similar shortage of scientific research evidence also surrounds the utility of criminal profiles. Assuming that the information contained within criminal profiles is accurate (i.e., valid), the next logical issue is to consider to what extent such information contributes, in terms of improved efficacy, toward the resolution of crime and thus utility for police investigators. The available research evidence on this issue has, thus far, largely come from surveys of police personnel. The outcome of these surveys (and thus the generally held view) is that criminal profiles do feature a productive role in assisting police investigations. However, gauging precisely how this is commonly and consistently achieved has proven difficult to clearly ascertain.

Criminal Profiling as Expert Witness Evidence

Although originally intended as a tool to assist with police investigations, the analytical techniques inherent to criminal profiling have made a gradual transition into the domain of expert witness evidence for use during court proceedings. Most Western common law jurisdictions throughout the world share the view that criminal profiling as traditionally performed is inadmissible as a form of expert witness evidence. The basis for this rejection is its probabilistic foundations. A fundamental doctrine to the admission of evidence in legal proceedings is that submitted evidence possesses a probative nexus (i.e., directly related and thus relevant) with the facts being judged before a court. This principle necessitates that the probative value of any evidence submitted before a court must outweigh any prejudicial impact that evidence may also hold. Within this legal paradigm, the correspondence that, for example, an accused person may share with a criminal profile does not possess sufficient probative substance. That is, while this correspondence may exist between the nominated features in a profile and

those of the accused, the predictions contained in a profile only pertain to the *type* of person who may have committed the crime. Thus, the criminal profile is unable to demonstrate that the accused person is the specific individual who committed the offense being tried before the court. For these reasons, criminal profiling has been rejected as evidence by superior courts of law.

In view of these judicial determinations, alternative modes of behavioral analysis that are derivations of criminal profiling have been explored as potentially admissible forms of expert witness evidence. Fact-based analyses of crime scenes, for example, reflect a subcomponent of the overall analytical process typically undertaken in criminal profiling but does not make predictions about the likely offender who perpetrated the crime. Thus, the submitted expert witness evidence only pertains to the interpretation of crime scene features (e.g., interpretation of car accident crash sites, blood spatter patterns, or gunshot wounds) specific to the case before the court.

CRIMINAL RESPONSIBILITY

This entry discusses the concept and attribution of criminal responsibility, the differences between criminal responsibility and moral responsibility, theoretical skepticism about the fairness of holding people responsible for their criminal behavior, and excuses in criminal law.

Murder, Manslaughter, Justification, and Excuse

Assume that your next-door neighbor, 25-year-old Bonnie, has been found dead. The police rule out suicide because there are multiple bullet wounds to Bonnie's head and chest. Somebody clearly killed her. Even if Bonnie was a bad person, most people think that whoever killed her needs to be punished. But why do they think this? And what, if anything, might change their minds?

Consider two further assumptions: Clyde was Bonnie's boyfriend, and an hour after arriving at her house, Clyde pulled out his gun, which he legally possessed, fired at Bonnie several times, and fled. Given these two additional assumptions, there are eight scenarios that might fill the gap between Clyde's arrival at Bonnie's house and the shooting.

Scenario 1: Bonnie broke up with Clyde, which enraged him.

Scenario 2: After drinking a lot of vodka, Bonnie and Clyde got into a heated political argument.

Scenario 3: After drinking a lot of vodka, Bonnie and Clyde got into a heated political argument. Clyde got so drunk that he blacked out. He genuinely does not remember either shooting Bonnie or fleeing her house.

Scenario 4: Clyde was a serial murderer. Bonnie was his 10th victim.

Scenario 5: Clyde found his conversation with Bonnie to be more boring than usual, so he decided that she no longer deserved to live.

Scenario 6: Clyde really did not want to kill Bonnie, but after a heated political argument, she pointed a gun at him. While she was firing at him, Clyde, trembling with fear, fired back.

Scenario 7: For the past year, Clyde periodically experienced paranoid delusions. At the time that Clyde shot Bonnie, he thought that she was an evil demon from another solar system who was planning to kill and eat little children.

Scenario 8: Clyde did not realize that death is permanent. He thought that Bonnie would—like Phil in the movie *Groundhog Day*—simply return from the dead the next day.

These scenarios can be grouped into five categories:

1. *Murder:* Scenario 1 (rage), Scenario 2 (drunken rage), Scenario 4 (psychopathic malice), and Scenario 5 (psychopathic indifference)
2. *Manslaughter:* Scenario 3 (blackout)
3. *Justified:* Scenario 6 (self-defense)
4. *Excused on the basis of insanity:* Scenario 7 (paranoid delusion)
5. *Excused on the basis of severe intellectual disability:* Scenario 8 (ignorance about death)

All five categories warrant different results. Category 1 warrants the highest sentencing range (long-term imprisonment or, in some states, the death penalty), Category 2 warrants a lower sentencing range, Category 3 warrants acquittal followed by release, and Categories 4 and 5 warrant acquittal followed by civil commitment.

Clyde is clearly *causally* responsible in all eight situations. But the fundamental question is whether he is *criminally* responsible. This latter kind of responsibility determination depends on *why* Clyde shot Bonnie, the psychological and external circumstances surrounding the shooting.

Responsibility Skepticism

The discussion so far has concerned only criminal responsibility, not moral responsibility. While the two kinds of responsibility are similar, they are not identical. A person (*P*) is morally responsible

for his or her action (A) when four conditions or elements are satisfied:

Element 1: P knew, or had a threshold capacity to know, both A's nature (what he or she was doing) and A's moral status (whether it was right or wrong).

Element 2: P had control, or a threshold capacity for control, over his or her A-ing.

Element 3: P could have refrained from A-ing.

Element 4: There is an absence of circumstances excusing P for A-ing—that is, an absence of circumstances making it unreasonable to expect P to have refrained from A-ing.

All four elements are satisfied in Scenarios 1–6 and therefore Categories 1, 2, and 3. (In Scenario 6, Clyde satisfied all four elements and is therefore *morally* responsible for killing Bonnie, but he is not *criminally* responsible because his action was justified under the circumstances.)

While most people accept the reality of moral responsibility—that is, they believe that Clyde is not only criminally responsible but also morally blameworthy for Bonnie's death in Categories 1 and 2—some philosophers, the *responsibility skeptics*, reject it. According to responsibility skeptics, moral responsibility is nothing more than a seductive, widespread illusion.

Responsibility skeptics deny the metaphysical possibility of moral responsibility on the basis of the powerful four-part *skeptical argument*. Part 1 of the skeptical argument says that there are only two logically possible alternatives: determinism and indeterminism. *Determinism* is the theory that the laws of nature plus initial conditions of the universe have necessitated every event, including every human's action. Conversely, *indeterminism* is the negation of determinism. If the world is indeterministic, then there are at least some events that are not determined; either they have no cause at all or they have a cause that does not necessitate—that is, *uniquely* determine or guarantee—them.

Part 2 says that determinism is incompatible with moral responsibility because it is incompatible with two conditions that are required for the latter: (a) the ability to do otherwise (i.e., the ability to have performed a different action) and

(b) ultimate self-causation (i.e., being the first or ultimate uncaused cause of one's actions). If determinism is true, then, despite appearances, individuals must always choose, decide, or act as they do, and they are never the ultimate—uncaused—causes of their actions. Instead, they are nothing more than *puppets* on the *strings* of whatever created the universe, whether the Big Bang or an eternal deity.

Part 3 says that indeterminism is equally incompatible with moral responsibility because indeterminism is not *self-determinism*. An *undetermined* choice, decision, or action is not a *self-determined* choice, decision, or action.

Part 4 wraps up the skeptical argument. Because determinism and indeterminism are the only two logically possible options, and because neither is compatible with moral responsibility, moral responsibility is logically impossible.

While one may have a strong intuition that Clyde *is* genuinely morally responsible in Scenarios 1–6—and genuinely morally *blameworthy* in Scenarios 1–5—the skeptical argument suggests that this intuition is simply wrong. Again, genuine moral responsibility or blameworthiness is equally incompatible with the only two logical possibilities, determinism and indeterminism.

What implications, then, for *criminal* responsibility? If Clyde is not genuinely *morally* responsible for killing Bonnie, then it seems grossly unfair to hold him *criminally* responsible—that is, to blame and punish him—in *any* scenario. Clyde is just as nonresponsible—and therefore should be just as immune from blame and punishment—in Scenarios 1–5 as he is in Scenarios 7 and 8.

This last point explains why some responsibility skeptics repudiate criminal punishment altogether. In place of *retributive justice* (i.e., intentionally inflicting suffering, hardship, or deprivation in response to prior criminal misconduct), they argue that the aim should be only for *restorative justice* (i.e., compensation by criminals to their victims, or victims' families, for the harms that they inflicted upon them). Their reason is that in addition to being more humane, restorative justice does not, like retributive justice, presuppose the highly contested concept of genuine moral responsibility. Instead, it assumes only causal responsibility plus an absence of force, coercion, or fraud.

Other responsibility skeptics, however, support *consequentialist* and *expressivist* justifications of criminal punishment. They suggest that the unfairness of pretending that criminals genuinely deserve blame and punishment is outweighed by society's need both to protect itself from them—through incapacitation, specific deterrence, and general deterrence—and to express its values through censure and stigmatization.

Social Causation

As noted earlier, discussions of moral responsibility and criminal responsibility tend to focus on the individual and his or her choices. For example, in evaluating Clyde, most would first determine which of the eight scenarios occurred, dig deeper into the circumstances and Clyde's psychology, and use this knowledge to arrive at a judgment about the extent, if any, to which Clyde was blameworthy for Bonnie's death.

What these analyses typically leave out are the external, mostly social, factors that (a) helped shape Clyde's psychology generally and (b) combined with this psychology to cause Clyde's violent behavior. Nobody lives in a vacuum; who we are—especially how we think and act—is largely, if not primarily, determined by environmental factors, including upbringing and culture (i.e., education, peers, social media, entertainment, and current events). The self is not an atom. It may have started that way (at conception or birth), but it increasingly and inexorably becomes part of a much larger molecule. While it retains its own distinct identity, personality, and life trajectory, these cannot be separated from the society into which this self was born. Each feeds into the other from birth to death. If any given person had been born into a different society, at least many of his or her beliefs, attitudes, values, decisions, and actions would be correspondingly different.

The idea that the self is partly determined and constituted by external factors arguably supplements the skeptical argument with yet another ground of universal exculpation. Now, Clyde can argue that society made him do it and that it was not really he, but rather society, who killed Bonnie.

There are, however, two assumptions underlying this argument, and both turn out to be false.

Assumption 1: Moral responsibility is a zero-sum game. If Clyde is morally responsible, then nobody else is; conversely, if society—the set of external influences on Clyde's beliefs, attitudes, values, decisions, and actions—is morally responsible, then Clyde is not.

Responsibility, however, is not a zero-sum game. Putting aside the skeptical argument, it seems perfectly possible that Clyde is fully morally responsible for Bonnie's death *and* that society is also at least partly morally responsible. Invisible in Scenarios 1–8 are all the values, norms, information, and experiences that helped to shape Clyde and to make him the kind of person who would carry a gun and kill Bonnie rather than refrain from engaging in such violence.

Assumption 2: *Tout comprendre, c'est tout pardonner.* (Rough translation: explanation is an excuse.) More precisely, the full causal or psychological explanation of a bad act necessarily amounts to a complete negation of moral responsibility for that act. Underlying this assumption are two deeper assumptions:

Assumption 2a: Fully explaining Clyde's act of killing Bonnie requires showing that Clyde's personality and circumstances uniquely determined it.

Assumption 2b: Both of these factors—personality and circumstances—are ultimately outside Clyde's control. He never freely chooses either of them.

From Assumptions 2a and 2b, it follows that

Assumption 2c: A full explanation of Clyde's act entails that Clyde could not have done otherwise; that, under the circumstances, he could not have refrained from killing Bonnie.

When a third assumption is added

Assumption 2d: The ability to do otherwise is necessary for moral responsibility.

one must conclude that Clyde is not morally responsible for killing Bonnie.

While both Assumptions 2b and 2d are seriously disputed by some philosophers, this entry (for the

sake of space) will discuss only the problem with Assumption 2a. Assumption 2a rests on its own deeper assumption that behavioral explanation requires the effect (action) to be uniquely determined by the cause (personality plus circumstances). But this deeper assumption does not reflect current practice. Behavioral explanation typically appeals to some combination of personal history, psychological states (i.e., reasons, beliefs, desires, intentions, plans, motives, attitudes, perceptions, and emotions), neurological conditions, use of mind-altering substances, and external circumstances. Whatever combination of these circumstances is assembled to explain a given action, it is not necessarily thought to *uniquely* determine the agent's behavior.

For example, in Scenario 1, the explanation of Clyde's behavior is that he flew into a rage after Bonnie ended their relationship. The rage explains the killing, and Clyde's personality in combination with Bonnie's ending the relationship helps to explain his rage, but it does not at all follow that these three factors—Clyde's personality, Bonnie's ending the relationship, and Clyde's rage—*uniquely* determined his homicidal response. One can easily hold constant these three factors and still imagine Clyde responding to his rage in different ways—for example, by yelling at Bonnie or storming out of the house. So here a causal explanation succeeds even though there is no demonstration that the cause *uniquely* determined the outcome.

Implications for Criminal Excuses

Applying the concepts of moral responsibility and criminal responsibility is especially difficult when the person is simultaneously a victim and a perpetrator. Consider criminal behavior caused in part by one of the following: (a) the *abuse excuse*: a plea for exculpation or mitigation based on a history of physical or sexual abuse or neglect; (b) post-traumatic stress disorder; (c) indoctrination into a violent ideology; (d) psychopathy, which is a neurological disorder resulting most notably in the inability to feel any compassion or concern for others; or (e) addiction or alcoholism.

Should any of these causes be considered exculpatory or mitigating? There are no easy answers to this question. The main reason for this difficulty is that most people's intuitions about how to

regard and treat perpetrators and how to regard and treat victims pull in directly opposite directions.

A secondary reason for this difficulty is that the perpetrator often causes significant harm, a fact that, rightly or wrongly, tends to override or diminish the weight one attaches to (a)–(e). In general, the more harmful the crime, the more sympathetic we are to the victims and the less sympathetic we are to the perpetrator. And the less sympathetic we are to the perpetrator, the less inclined we will be able to view whichever cause is operative as exculpatory or mitigating.

This point about the tension between responsibility attributions on the one hand and harm on the other explains why the excuses—automatism, duress, entrapment, infancy, insanity, involuntary intoxication, mistake of fact, and mistake of law—are often rejected. Each of these excuses says that, sympathetic as the judge or jury may be to the victims, they still cannot justifiably blame the defendant for the harm that he or she inflicted on these victims. This is a tough position for fact finders to be in. As a result, defendants who offer excuses for their criminal behavior are in a tough position as well. They have to persuade judges and juries that the unfairness of blaming or punishing them outweighs the unfairness of the harms that they inflicted on their victims. Given most people's retributivist sentiments—their strong sense that, one way or another, the defendant must pay for what he or she did—this plea is too often a lost cause.

CRIMINAL RISK ASSESSMENT, CLINICAL JUDGMENT OF

Clinical judgment in the assessment of offender risk contrasts with mechanical assessment. When clinical judgment is used, the assessment is based on clinical observations or experience, formal theory or informal hypotheses about criminal behavior, grasp of the current status of research on risk assessment, or similar intuitive understandings of risk. Clinical judgment can also be used following the completion of a mechanical or otherwise structured assessment of previously selected risk factors, commonly referred to in the criminal risk assessment field as *structured professional judgment*. This entry briefly compares unaided clinical risk assessment with mechanical risk assessment tools and considers the nature and role of structured clinical judgment in current risk assessment approaches.

Clinical Judgment Compared With Mechanical Assessment

Clinical judgment in the absence of a formal procedure or guide to conducting an assessment is known as *unstructured* or *unaided clinical judgment*. It maximizes the use of intuition, which itself may be influenced by the individual assessor's experience with similar cases as well as the assessor's attention to, memory for, and ability to integrate feedback from the outcome of previously assessed cases. In this way, the assessor inevitably draws upon a broad class of offenders to generalize to the individual case.

In contrast, mechanical risk assessment uses a preselected collection of risk factors and derives a total score based on the item scores. Alternatively, mechanical risk assessment might classify risk based on a cutoff score or the presence of certain items. The numeric or categorical result of a mechanical risk assessment tool is used, in the case of actuarial tools in particular, to refer to a chart of absolute (i.e., probability) and relative (i.e., percentile rank) risk of reoffending. These statistics are derived from follow-up studies of large samples of offenders and are used to inform decisions about risk management at the individual or policy level.

The Current Status of Unaided Clinical Judgment

Unaided clinical judgment is no longer considered an appropriate method of risk assessment because of its poor reliability and validity. Research indicates that assessors who use unaided clinical judgment do so inexpertly: They show little agreement with each other, they do not predict criminal outcomes well (especially when predicting that violence will occur), and even experienced and highly trained clinicians use the same kinds of information about an offender that educated laypersons use to assess offenders' risk of reoffending. In addition, unaided clinical judgment shows poor predictive validity. In 2001, John Monahan and colleagues decried the prospect of further research into the validity of unstructured clinical assessment, declaring "That horse was already dead" (p. 7).

Clinical Judgment in Structured Risk Assessment

Some offender risk assessment procedures combine a mechanical approach with a summary rating of risk based on overall clinical judgment. In these structured instruments that incorporate clinical assessment, the risk factors might be scored to derive a total that informs the clinical judgment, or the clinical judgment might be a more intuitive deduction of risk based on all the information previously considered. The final judgment is expressed in terms of a category such as *high risk*, *moderate risk*, or *low risk*. Depending on the type of assessment, the assessor might judge the risk of a specific outcome such as sexual violence or violence against an intimate partner. Clinical assessment might also be used to judge the severity or imminence of a criminal outcome. In any case, use of structured clinical judgment in criminal risk assessment results in the use of categorical, nonnumerical methods of risk communication.

Some risk factors on a mechanical risk instrument might themselves require clinical assessment skills. For example, it is common for instruments to include items pertaining to psychopathy or mental illness in offender risk assessment. These measures might require psychological testing and diagnostic skills. When clinical judgment is used to administer a mechanical risk assessment tool, it

only contributes to the evaluation of specific items and is not used to adjust the total score. Thus, assessment tools that incorporate clinical judgment differ from strictly mechanical risk assessment tools most substantially in the extent to which clinical judgment is used in deriving the final appraisal of an offender's risk.

Another key characteristic of tools that use structured clinical assessment is that they might incorporate risk factors on the basis that they are theoretically informed, rather than only items selected through their empirical relationship with criminal outcomes. Such tools may also encourage assessors to consider additional or unusual factors that are thought to contribute to offending behavior in the individual being assessed.

Using Clinical Judgment in Forensic Decision-Making

Following risk assessment, some professional judgment is necessary to determine how to intervene with criminogenic needs or take other steps toward risk management because no existing offender risk assessment tool indicates the decisions that must be taken to prevent offending. Treating an offender as higher risk than indicated by a structured risk assessment tool is acceptable in exceptional circumstances, such as a credible threat made by an offender to physically harm another person. Furthermore, when the predictive validity of a mechanical risk assessment is less than optimal, adding an overall clinical judgment has the potential to improve risk assessment. However, routine adjustment of structured risk assessment using clinical judgment is not supported because clinical overrides have been shown to reduce the accuracy of validated risk assessments in several studies.

CRIMINAL RISK ASSESSMENT, COMBINED STATIC AND DYNAMIC APPROACHES TO

Mental health practitioners are often asked to provide an opinion on the likelihood that an individual will become aggressive or violent, as the criminal justice system aspires not just to punish past criminal behavior but also to reduce future criminal behavior. Formalized *criminal risk assessments* are one approach to determining and assessing relevant risk factors in order to estimate the probability of reoffending and developing plans to minimize risk. *Risk factors* refer to personal and environmental characteristics that are shown to be associated with an increased risk of future criminal behavior. *Static* risk factors are those that do not change over time, generally historical information or other factors unchanged by intervention, whereas *dynamic* risk factors are those that could possibly change, and they are generally considered more amenable to intervention.

Criminal risk assessment strategies are beneficial in a number of contexts including, but not limited to, informing courts, and assessing supervision and treatment needs. More specifically, the issue of criminal risk assessment commonly arises to aid the courts in making legal decisions such as whether to grant bail or parole, sentencing, and civil commitment. A high-risk individual, for example, may have different supervision requirements with regard to probation, parole, or possible civil commitment than someone deemed low risk of reoffending. The emphasis placed on

treatment involvement may also vary depending on presenting risk factors and level of risk.

Given the vast implications and significant impact, not only on the community but also on the individuals being assessed, accurate and efficient prediction remains the ultimate objective. Since 2005, there has been a significant increase in the amount of research dedicated to understanding theories of violence, predicting violence, and improving risk assessment procedures. Many instruments, some of which are discussed in this entry, have been created with the goal of improving accuracy in the process of violence and/or sexual risk prediction.

Static and Dynamic Risk Factors

Researchers and evaluators conceptualize risk factors in two groups: static and dynamic factors. Static, or fixed, risk factors include historical information that will remain constant across time. Dynamic, or changeable, risk factors are those that are modifiable with interventions. It is important for practitioners to keep both types of risk factors in mind when conducting a risk assessment (see Table 1).

Static Risk Factors

One static risk factor that is a strong predictor of future risk is a history of violence. Research suggests other relevant static risk factors include male gender, younger age, and an extensive criminal record. Some researchers argue that static risk factors are more useful for identifying long-term risk; however, static risk factors are often deficient in being able to predict or indicate when violence or aggression may occur. Furthermore, many researchers emphasize that static risk factors are not generally useful in determining potential change in risk over time.

Dynamic Risk Factors

It has been suggested that dynamic risk factors are vital to criminal risk assessment because they can assist in identifying those individuals who are the best candidates for intervention. Examples of dynamic risk factors include the following: interpersonal relationships at home, school, or work; level of association with delinquent peers or associates; and antisocial attitudes and/or personality.

Table 1 Common Risk Factors Associated With Greater Risk

Static Risk Factors	Dynamic Risk Factors
Younger age	Antisocial personality pattern
Male	Violent attitudes or thoughts
Criminal history	Antisocial associates
History of antisocial behavior	Family or marital instability
Younger age at index offense	School and/or work environment problems
Employment instability	Low participation in leisure and/or recreation activities
	Substance abuse
	Symptoms of mental illness
	Low participation in treatment
Additional Sexual Risk Factors	
Younger age of victim	
Male victim	
Unrelated victim	

Note. This list identifies the most common empirically-supported risk factors associated with a greater likelihood of violence and/or sexual recidivism.

Dynamic risk factors can further be differentiated into *stable dynamic* risk factors and *acute dynamic* risk factors. Stable dynamic factors are those risk factors that are generally enduring characteristics (e.g., problems related to substance abuse, antisocial personality). These are likely to remain unchanged for months or even years. It has been argued that interventions with the goal of creating lasting improvements should target stable dynamic risk factors. Acute dynamic factors are those risk factors that are more rapidly changing and might immediately precipitate the perpetration of an offense (e.g., intoxication, negative mood). These may last days, hours, or even minutes. While acute dynamic risk factors are specifically related to the timing of offending behavior, they may have little connection with long-term risk likelihood.

Some dynamic risk factors that show a negative relationship with reoffending are categorized as *protective factors*. In other words, the presence of these factors appears to reduce the risk of future violent behavior. These can be personal characteristics or environmental/situational characteristics. Some protective factors are conceptualized as the opposite of a known risk factor (e.g., impulsivity vs. self-control; stress vs. coping). Other risk factors are the absence of a behavior or characteristic, and therefore, the protective factor is the presence of the behavior or characteristic (e.g., intimate relationships, participating in prosocial leisure or recreational activities). Some protective factors (or, rather, the lack thereof) have been found to predict future violence even when risk level was controlled.

Risk Assessment Measures

Static-Only Measures

Violence Risk Appraisal Guide–Revised (VRAG-R)

The VRAG-R is a 12-item actuarial measure of static factors of violence risk. Items include those related to psychosocial history (i.e., elementary school maladjustment, lived with both parents, and marital status), criminal history (i.e., admission to corrections, failure on conditional release, nonviolent criminal history, violent criminal history, sexual offending, and age at index offense), and

psychopathology (i.e., antisociality, conduct disorder, and substance abuse). Each item is given a weighted value based on the item's ability to discriminate between those who recidivate and those who do not recidivate. Total scores on the VRAG-R range from -25 to $+27$; based on this score, offenders are placed into one of nine bins with higher numbered bins associated with a stronger likelihood of violence.

Psychopathy Checklist–Revised (PCL-R)

The PCL-R is a 20-item measure of static factors examining an individual's history of Interpersonal, Affective, Lifestyle, and Antisocial characteristics related to psychopathy. The PCL-R is measured on a 3-point scale (0–2) with a traditional cut score of 30, reflective of psychopathy. Although the PCL-R was not initially developed as a measure of violence risk, research has consistently linked the two concepts. In addition to the PCL-R, there is a shortened version and a version for adolescents, both of which are often used in violence risk assessments.

Static-99R

The Static-99R is a 10-item actuarial risk assessment measure of static risk factors related to sexual recidivism. Scores on the Static-99R range from -3 to 12 , which places the individual in one of four risk categories: low (-3 to 1), moderate-low (2 to 3), moderate-high (4 to 5), and high (6 or higher). Research suggests that the Static-99 is one of the most commonly utilized measures of sexual recidivism risk among mental health practitioners, particularly those who conduct sexually violent predator evaluations for civil commitment proceedings. There is an updated version of this measure, the Static-2002R, which has additional items and separates individuals into one of five categories. Research is contradictory, however, on whether the 2002 version has any improved accuracy compared with its predecessor.

Rapid Risk Assessment for Sex Offense Recidivism

The Rapid Risk Assessment for Sex Offense Recidivism is a 4-item assessment tool for determining sexual recidivism risk among adult males

who are known to have committed at minimum one sexual offense. The 4 items include the number of prior charges or convictions for sexual offenses, age upon release from prison or the anticipated opportunity to reoffend in the community, any unrelated victims (coded as yes or no), and any male victims (coded as yes or no). Scores on this measure range from 0 to 6.

Static and Dynamic Measures

Historical, Clinical, Risk Management-20 (HCR-20), Version 3

The HCR-20, Version 3 is a measure of violence risk that relies on structured professional judgment. It includes 20 items. Ten of these items (Historical) are static, and 10 (five Clinical and five Risk Management) are dynamic. The Historical variables examine characteristics of the individual that are stable and unchanging (e.g., having a history of violence or antisocial behavior, history of problems with employment, and history of substance abuse). The Clinical variables include information about the individual's current mental status (e.g., problems related to insight, symptoms of a major mental disorder, recent problems with violent ideation or instability) and the Risk Management variables examine environmental factors (e.g., problems related to their living situation, problems related to treatment or supervision). Each item is scored on a 3-point scale (0–2; *absent, partially present, definitely present*) with higher scores indicating the presence of the risk factor. A total score can be calculated (maximum score of 40), but the authors urge clinicians to integrate the variables into a final determination of violence risk (*low, moderate, high*).

Sexual Violence Risk-20 (SVR-20)

The Sexual Violence Risk-20 (SVR-20) is a 20-item checklist of both static and dynamic risk factors associated with future violence and SVR. Items on the Sexual Violence Risk-20 SVR-20 fall into one of three categories: Psychosocial Adjustment (i.e., sexual deviance, victim of child abuse, substance use problems, psychopathy, major mental illness, suicidal/homicidal ideation, and relationship problems), History of Sexual Offenses (i.e., high-density multiple types, physical harm,

weapons/threats, escalation in frequency or severity, extreme minimization/denial, attitudes that support or condone), and Future Plans (i.e., lacks realistic plans and negative attitude toward intervention). Clinicians rate each item based on degree of risk for this defendant as *low, moderate, or high*.

Minnesota Sex Offender Screening Tool–Revised (MnSOST-R)

The Minnesota Sex Offender Screening Tool–Revised includes 16 items related to both static (e.g., age, presence of adolescent antisocial behavior, nonsexual and sexual criminal history) and dynamic risk factors (e.g., current/recent employment instability, current/recent substance abuse, and current/recent sex offender treatment) for sexual recidivism. Scores on the MnSOST-R range from –14 to 30. The total score results in the assignment to one of three levels of risk: Level 1 (low risk, scores of 3 and lower), Level 2 (moderate risk, scores of 4 to 7), or Level 3 (high risk, scores of 8 or higher). The developers of the MnSOST-R also developed a subset of Level 3 (scores of 13 or higher), in which it is recommended individuals with these scores should be referred for commitment proceedings. The MnSOST-R is commonly used among mental health practitioners conducting sexually violent predator evaluations.

Dynamic Only Measures

Structured Assessment of Protective Factors

The Structured Assessment of Protective Factors for violence risk focuses on dynamic, protective factors affecting violence risk (only 2 items on the measure examine static factors). It was created as a complement to the HCR-20's risk factors and is used together with that measure. Similar to the scoring design of the HCR-20, the Structured Assessment of Protective Factors has 17 items that are scored on a 3-point scale (0–2) with higher scores indicating the presence of protective factor. These 17-items are categorized under one of three scales: Internal Factors, Motivational Factors, and External Factors. Clinicians can also score a Final Protection Judgment (*low, moderate, high*) based on an

integration of the protective factors. Furthermore, clinicians can examine an integrated Final Risk Judgment by integrating the Final Protection Judgment with the HCR-20 risk scores to determine a risk of future violent behavior.

Use of Static and Dynamic Risk Factors

The aforementioned measures are the most empirically supported and do not constitute every violence or sexual recidivism risk measure that exists. Based on available research, the HCR-20, VRAG-R, and the Static-99 appear to have the most empirical support. Other measures, such as the Classification of Violence Risk and the Short-Term Assessment of Risk and Treatability, exist but have less research support or have been validated using a limited sample population.

Meta-analyses have found few differences in violence risk prediction across measures. Overall, the aforementioned measures moderately predict violence risk. While this suggests that each of these measures is interchangeable, it is important for clinicians to keep in mind the individual and the situation when choosing a risk assessment measure. Furthermore, although research has not found differences between measures of only static factors versus measures that include dynamic factors, these measures serve differing purposes. Measures that include dynamic factors allow clinicians to assess for changes in risk level over time or based on situation, whereas measures using only static factors do not allow for change. In conducting comprehensive risk assessments, clinicians are on solid ground to rely on both historical and dynamic variables. Such an approach provides the most valid predictions of risk.

CRIMINAL RISK ASSESSMENT, DOMESTIC VIOLENCE

Domestic violence risk assessment is the evaluation of characteristics of an offender, offense, or other circumstances considered relevant to the risk that an offender will commit a domestic violence offense in the future. Whether information is considered relevant and how it is weighed depend on the approaches taken to risk assessment. In the two leading approaches, these decisions are based either on empirical research leading to actuarial data that permit individual risk to be estimated using the strongest predictors known for the offender population or on a broader assessment of the individual leading to an overall judgment of

risk or a clinical case formulation. Domestic violence risk assessment is important to the extent it aids the risk principle of the Risk-Need-Responsivity model to be carried out. All approaches to domestic violence risk assessment have in common the intention to identify priorities for responding to offender risk, whether in terms of criminal justice intervention, offender treatment, or other forms of risk management.

Domestic violence risk assessment is different from screening, which is used to identify individuals who might be experiencing abuse. It is also different from the function of risk management, in which attempts are made to mitigate the likelihood of an offense occurring among offenders identified at risk of domestic violence.

This entry provides a context for domestic violence in relation to other criminal behavior, describes the most widely researched specialized risk assessment instruments, and looks to future research avenues for further applications.

Domestic Violence and Other Criminal Behavior

Developments in the assessment of risk of domestic violence followed on the success of research constructing and validating tools to predict violent and sexual recidivism (reoffending). The two fields share certain challenges, including reliance on official charges or convictions (an exception being some research on the Danger Assessment, described in the next section, which was developed for its ability to assess risk of self-reported victimization). Criminal charges substantially underrepresent the actual occurrence of offending. In addition, the qualifier of *sexual* or *spousal* is often omitted or dropped from assault and similar charges, making it difficult to determine whether or not the outcome criteria have been met. When cases with ambiguous recidivism (e.g., the victim of a new offense cannot be determined from available evidence) are excluded from analysis, predictive accuracy increases. Another approach is to compare only offenders known to recidivate domestically with those who only reoffend against nonintimate partners. However, this approach might obscure domestic offenders' criminal diversity, for which there is growing empirical evidence that might be pertinent to assessing domestic violence risk.

Domestic Violence Risk Assessment Instruments

Danger Assessment

The first specialized domestic violence risk assessment to be published and evaluated was the Danger Assessment, which appeared in the mid-1980s. The intention in creating the Danger Assessment was to help women evaluate their risk of being killed by an abusive male partner. The instrument was designed to be used as part of a structured interview, combining a calendar-based assessment of the history of domestic violence with a 20-item risk assessment tool, revised from an original 15 items. The items cover information such as the history of violence, threats, and other abuse, weapons, substance use, and suicidal histories of the offender and victim. Scores on this tool are used to classify risk as variable, increased, severe, or extreme danger. Several studies have shown that scores on the Danger Assessment are associated with subsequent domestic violence recidivism as well as with the severity and type of abuse (e.g., intimate partner sexual assault). The Danger Assessment is also associated with victim outcomes, including depression, post-traumatic stress disorder, substance use, and taking precautions for safety from the violence. The Danger Assessment has been modified based on research for different populations, including immigrant women and women in same-sex relationships. In case-control research, the Danger Assessment score has been found to distinguish between women who were killed and women who were abused but not killed.

Spousal Assault Risk Assessment Guide (SARA)

The SARA, intended for assessing the risk of domestic violence perpetration, first appeared in the 1990s. This instrument was designed to be used after gathering information on the offender from official reports as well as offender and possibly victim interviews. The 20-item risk assessment tool covers information such as the offender's history of violence and criminal justice violations, childhood abuse, mental disorder, threats, weapons, substance use, and suicidal history. The assessor uses this tool, as well as items or other information determined to

be critical, to classify risk as low, moderate, or high. The SARA has been validated as a predictor of domestic violence recidivism in several studies using the total score or the summary risk judgment. In 2015, a revision was released that added items pertaining to victim vulnerability and omitted the item scoring procedure in favor of a clinical case formulation approach. In this SARA-V3, assessors are encouraged to identify factors that might motivate, disinhibit, or destabilize violent behavior as well as the scenarios under which violence might occur. Opinions are then offered as to management plans, case prioritization, and the risk of violence or other outcomes. This theoretical conceptualization approach requires more expertise and analysis than might be practicable for frontline policing or other first responders such as those working in shelters or emergency departments.

Brief Spousal Assault Form for the Evaluation of Risk (B-SAFER)

Related to the SARA is the B-SAFER that was designed for frontline use in the criminal justice section. The original 10-item risk assessment tool covers information such as the offender's history of violence and criminal justice violations, mental disorder, threats, substance use, and employment; 5 items were later added concerning victim vulnerability. Initial research showed that scores on the B-SAFER can predict subsequent domestic violence.

Ontario Domestic Assault Risk Assessment (ODARA)

The first specialized domestic violence risk assessment tool to be developed using statistical methods was the ODARA. This instrument was designed to be used by police officers during a domestic violence investigation and as a guide to conducting a victim interview to obtain the information that was subsequently developed for use in victim support services. The 13-item risk assessment tool covers information such as the offender's history of violence and criminal justice involvement, threats, weapons, substance use, and victim barriers to support. Each item is scored 0 or 1, and the total score is used to compare an offender with others in terms of risk of domestic

violence recidivism, using an actuarial table that contains statistical data from a large follow-up study of outcomes. Several validation studies have been conducted that support the ODARA's ability to assess domestic violence recidivism risk in police and correctional cases. Some research has found that the ODARA score is also associated with co-occurring child abuse and with nonviolent, nondomestic violence, and other criminal outcomes by domestic offenders.

Domestic Violence Risk Appraisal Guide

Related to the ODARA is the Domestic Violence Risk Appraisal Guide that was designed for use when greater time and resources are available. It was created through research revealing that predictive accuracy could be improved by combining the ODARA items with the Psychopathy Checklist-Revised. In cross-validation research, the Domestic Violence Risk Appraisal Guide was associated with domestic violence recidivism and with the subsequent number of incidents, victim injury, severity, and seriousness of criminal charges.

Domestic Violence Screening Instrument-Revised (DVSI-R)

The algorithmic and professional judgment methods of assessing risk are combined in the DVSI-R. This instrument was designed to be used by probation officers. The original 12-item risk assessment tool was developed using large-scale empirical research identifying characteristics of offenders with a history of domestic violence; these characteristics were selected as items if they were also associated with repeated domestic violence in a literature review. It was revised to 11 items following further empirical research. The resulting DVSI-R covers information such as the offender's history and current violence, arrests and convictions, criminal justice violations, weapons, substance use, and employment status. Items are scored on a 3- or 4-point scale and summed for a total score. The assessor also uses this tool to classify risk as low, moderate, or high. Validation research has replicated the predictive effect of the DVSI-R for family violence and other domestic incidents, and the score has yielded a

significantly larger effect size than the professional judgment.

A Different Approach to Domestic Violence Risk

There is a growing capacity for criminal justice systems to develop risk assessment procedures based on their offender processing and tracking databases. Richard Berk and colleagues reported in 2016 that data from over 28,000 cases involving arrest for domestic violence were used to generate an algorithm to forecast those who would have no further detected domestic violence incidents in a 2-year follow-up. Most offenders met the criterion for nonrecidivism, and they could be identified with nearly 90% accuracy. The tool is used to classify, at the time of arraignment, offenders who can be swiftly processed for bail in order to allow more resources to be allocated to further assessment or intervention for offenders who pose a risk of recidivism. This approach permits the use of statistical modeling techniques more robust than those typically used to develop actuarial risk assessment tools, and the big data set also means that the process can be continually refined. Because it is constructed using data from the intended population and used to inform decisions in that same population, this approach is a good example of implementing the Risk-Need-Responsivity risk principle.

Cross-Validation and Generalization of Domestic Violence Risk Assessment

Empirically derived risk assessment instruments are sometimes criticized for the expected loss of predictive accuracy between construction and cross-validation. Nonalgorithmic assessments have been opposed for their inclination toward unstructured clinical opinion. For any risk assessment approach, there is a need to evaluate and replicate the extent to which a measure is related to the outcome of interest. Research has been conducted to demonstrate the generalizability of most of the major published domestic violence risk assessment instruments for male offenders. Research with some of the tools described in this entry has shown that they are associated with police decision-making, but field-testing of

domestic violence risk assessment remains in its infancy.

Limited research, in contrast, has been conducted with female offenders. One study of police using the B-SAFER found that fewer than 10% of women were judged to be high risk. Research with women in same-sex relationships led to a revision of the Danger Assessment to improve predictive accuracy for this group. A small study of the ODARA and a large study of the DVSI-R found that these instruments predicted women's domestic violence recidivism, but their overall reoffense rates were lower than men's.

Risk assessment for victims has been particularly concerned with their risk of homicide by an intimate partner. Both the Danger Assessment and ODARA have been reported to yield relatively high scores in domestic homicide cases. However, statistical modeling of homicide risk is impeded by the low base rate of such cases. Cooperation among sectors responding to domestic violence, and the sharing of information from validated domestic violence risk assessment, has been recommended as the most promising approach.

CRIMINAL RISK ASSESSMENT, GENDER-RESPONSIVE

In correctional settings, risk assessment serves to classify offenders by their likelihood of future offense-related behavior and misconduct by identifying predictive factors. These risk factors are often also referred to as *criminogenic needs* and can be static (i.e., stable over time) or dynamic (i.e., change over time). Dynamic criminogenic needs present an opportunity for treatment to reduce the risk of reoffending. A large body of literature has identified a number of valid predictive factors based largely on research with male offender samples; however, research also shows that women's criminogenic needs are different than those of male offenders and require variation of priority in treatment. Using gender-responsive risk assessments that address risk factors and criminogenic needs that are particularly crucial among female populations is key to developing appropriate treatment targets for women offenders and ultimately to reduce recidivism (reoffending). Risk factors particularly relevant to women offenders and the policy implications of women's criminogenic needs and risk levels are discussed in this entry, along with the theoretical background leading to the emergence of this research and the development of a gender-responsive risk assessment tool.

Risk Factors and Policy Implications

As suggested by the well-known Risk-Need-Responsivity model of correctional intervention put forth by D. A. Andrews and James Bonta, once dynamic need factors (e.g., antisocial personality, attitudes, and associates) become recognized as measures of risk, and they can become targets of criminal justice or mental health treatment interventions in an attempt to reduce the likelihood of reoffending. However, critics argue that existing gender-neutral (those based on male samples but applied to women as well) risk-need assessment tools such as the Level of Service-Revised and Level of Service/Case Management Inventory that were developed by using gender-neutral social learning, behavioral, and personality theories, and primarily male samples do not adequately account for women's distinct criminogenic risk and needs. Consequently, factors that can actually enhance

efforts to predict recidivism among female offenders were overlooked or categorized as lower priority-specific responsivity-related needs.

In contrast to the *big four* predictive factors (criminal history, antisocial attitudes, personality, and associates) well-known in risk assessment research using largely male samples, research focused on women offenders identifies the most important criminogenic needs as substance abuse, mental health, housing, education, employment, and financial issues (in terms of more traditional gender-neutral factors). Furthermore, this research has not found criminal attitudes to be a consistent predictor of offense-related outcomes for women. This suggests a different set of priority areas to be targeted for the reduction of further offending.

Some widely known criminogenic needs have been found to affect women differently than men and, thus, must be identified and targeted for intervention through modified methods. Additionally, gender-responsive criminogenic needs vary slightly by setting. For instance, factors predictive of institutional misconduct include family and relationship factors, childhood victimization, and mental health. On the other hand, factors predictive of outcomes in community settings while including similar factors extended to adult victimization and issues of safe housing, self-esteem, and self-efficacy.

Similar to changes in prioritization of criminogenic needs among female offenders, a shift in the prioritization of treatment targets must also occur. Treatment of women offenders should focus on unhealthy relationships, relevant services for substance abuse, mental health (including trauma), and improving socioeconomic status and should facilitate community connections to services. This requires well-coordinated provision of wraparound services, which involves case management with multiple resources at all stages of correctional processing (incarceration, prerelease, and in the community).

Another important revelation brought about by recent advances in the development of gender-responsive assessment is that women's risk of institutional misconduct and reoffending is lower than that of men in general, commonly referred to as the *gender-ratio problem*. Furthermore, the seriousness of misconduct and offenses committed by women is lower as well. Consideration of these differences in women's correctional environments and treatment plans would thus be appropriate

under the Risk-Need-Responsivity model of correctional intervention.

Theoretical Background

In addition to the Risk-Need-Responsivity model, the foundation of gender-responsive assessments lies in the theoretical and empirical implications within the gendered pathways perspective. Stemming from the work of feminist scholars and criminologists, such as Joanne Belknap, Meda Chesney-Lind, Kathleen Daly, Barbara Bloom, Barbara Owen, and Stephanie Covington, the pathways perspective stresses the importance of focusing on female offenders' distinct *pathways to crime*, which are not accounted for by mainstream criminological theories. Thus, the foundation of the pathways' perspective lies in theories addressing social and psychological issues distinctive to female offenders including trauma theory, relational theory, holistic addiction theory, and social capital theory. Gendered pathways research highlights life histories of female offenders that often entail physical and sexual abuse, trauma, mental illness (e.g., depression, anxiety, borderline personality disorder, and post-traumatic stress disorder), self-medication through substance abuse, unhealthy relationships, parental stress, economic marginality, and low levels of self-esteem and self-efficacy.

Women's Risk-Need Assessment (WRNA)

With compiled evidence of differential needs for women offenders, the National Institute of Corrections partnered with University of Cincinnati to develop a gender-informed risk and need assessment tool, the WRNA, to advance treatment of dynamic risk factors for women with a gender-responsive model of service provision. In addition to producing a trailer version (WRNA-T) to function as an adjunct to existing risk-need assessment tools such as the Level of Service-Revised and Correctional Offender Management Profiling for Alternative Sanctions, a full stand-alone version was also developed with options for institutional and community settings.

The WRNA instrument measures criminogenic needs that are more prevalent among women offenders, in addition to gender-neutral items framed upon women's experiences. The

instrument focuses on abuse and related trauma, parental stress, unhealthy relationships, anxiety and depression, personal safety, and personal strengths. Gender-neutral items include substance abuse, housing (including personal safety at home), mental health (including mood disorders), and family relationships (including parental stress, family background, and intimate relationships). Antisocial attitudes and cognitions were reframed as measures that include self-esteem and self-efficacy. Several factors (self-esteem, self-efficacy, educational assets, and support from others) are also measured as strengths to indicate sources of leverage to be utilized in treatment plans.

The WRNA is a reflection of a growing body of evidence that demonstrates that the nature of offending behavior and rehabilitation is different between women and men. This knowledge can better inform research and practices within the criminal justice system and improve behavioral outcomes for justice involved women and girls.

CRIMINAL RISK ASSESSMENT, GENERAL OFFENDING

Criminal risk assessment refers to the process of predicting an individual's risk of future criminal activity. The purposes of criminal risk assessment

are to identify those individuals at higher risk of future offending and inform interventions designed to reduce an individual's risk of future offending. Risk assessment is utilized in a variety of contexts, both criminal and noncriminal. In criminal contexts, criminal risk assessment is used to inform legal and correctional decisions across the criminal justice spectrum, including during pretrial detention/bail, juvenile transfer, and sentencing (state, federal, and capital); determining security levels for prisoners; determining appropriate probation/parole supervision conditions; and reentry planning. In noncriminal (civil) settings, risk assessments are used to predict an individual's potential for violence in the workplace, determine whether a sex offender is a sexually violent predator, and determine whether someone should be civilly committed. This entry provides a history of risk assessment and a detailed examination of its four major approaches developed across time: unstructured clinical judgment, anamnestic assessment, actuarial assessment, and structured professional judgment (SPJ).

The process of criminal risk assessment involves identifying and weighing both factors that increase the likelihood that someone will commit future criminal activity (risk factors) and factors that reduce the likelihood that someone will commit future criminal activity (protective factors). Both risk and protective factors can be either static (unchangeable) or dynamic (can be modified through targeted interventions). For example, criminal history is a static risk factor because it cannot be changed, while substance use and making poor use of leisure time are dynamic risk factors because they can be addressed through appropriate interventions. Intelligence is an example of a static protective factor; conceivably, barring some type of brain injury or neurodegeneration, an individual's level of intelligence is stable across the life span. By contrast, social support is a dynamic protective factor because individuals can increase their levels of social support.

Risk and protective factors can be biological, psychological, or sociological in nature. Examples of biological risk factors include chemical deficiencies in enzymes such as monoamine oxidase, which is associated with increased aggression, or dysfunction in neurochemicals such as serotonin, which is linked to aggression and impulsivity.

Examples of psychological risk factors include the presence of certain personality disorders or constructs associated with antisocial behavior, such as psychopathy, conduct disorder, or antisocial personality disorder. Examples of sociological risk factors include poverty or exposure to negative peers. In contrast, examples of biological protective factors include strong executive functioning capabilities, psychological protective factors include high self-esteem or interpersonal warmth, and sociological protective factors include participation in prosocial activities, such as community-based sports or religious services.

Approaches to Risk Assessment

Across the history of criminal risk assessment, four approaches to risk assessment have predominated: unstructured clinical judgment, anamnestic assessment, actuarial assessment, and SPJ. Understanding these various methods provides an informative mapping of the evidence-based evolution of risk assessment and the benefits and challenges of each approach. Current trends advocate for a blend of these approaches, along with choosing a risk assessment tool based on the goals of the assessment (e.g., risk prediction vs. risk reduction) and the individual being assessed. The various methods of conducting risk assessments have been debated, scrutinized, and studied, so there is a large body of scholarly and empirical literature on risk assessment. Moreover, the legal field is paying increased attention to risk assessment in both criminal and civil contexts.

Unstructured Clinical Judgment

The unstructured clinical judgment approach consists of a mental health professional's use of clinical judgment without the assistance of risk assessment tools or measures. Using clinical judgment that has been developed through experience, practitioners reach an opinion regarding an individual's risk of committing future criminal activity. Of the four approaches to risk assessment, the unstructured clinical judgment approach has the least amount of empirical support in terms of accurately predicting future offending behavior. Specifically, unstructured clinical judgment tends to lead to Type I errors (false positives). Thus,

when utilizing their discretion, clinicians will tend to inaccurately conclude that an individual has a higher risk of committing a criminal act in the future than is actually warranted. Unstructured clinical judgment is significantly less effective at predicting risk-relevant outcomes than the other approaches to risk assessment. As such, best practices suggest avoiding this type of criminal risk assessment.

Actuarial Assessment

Actuarial risk assessment involves using equations, formulas, or other actuarial methods to arrive at a probability that an individual will engage in future criminal activity. As it pertains to offending generally, the risk assessment literature has highlighted certain factors that are empirically associated with specific outcomes. For example, factors such as history of violence, certain personality traits or disorders, and substance abuse are robustly related to future offending. In actuarial risk assessment, combinations of risk factors are used to determine an individual's risk level (e.g., low, medium, high, very high). One such instrument is the Level of Service Inventory-Revised, which measures the presence of risk factors across 10 domains to derive a risk estimate. By comparing the risk scores in each domain and the total risk score to those of the Level of Service Inventory-Revised normative sample, individuals can be categorized into a risk level that is associated with a percentage likelihood of offending. Although substantially more reliable than risk assessment using unstructured clinical judgment, actuarial risk assessment has been subject to criticism for its lack of attention to individual considerations when drawing risk conclusions. In addition, evidence suggests that all actuarial measures are roughly equivalent in predicting future criminal behavior as long as the measure is empirically supported and provides guidance on score differentiation and risk-level categorization.

Anamnestic Assessment

Whereas actuarial assessment provides key domains as risk factors in predicting the probability of future offending behavior, the anamnestic approach to risk assessment provides risk factor

domains using an individual's history. Under the anamnestic approach, forensic mental health professionals review the individual's history of previous antisocial behavior to derive risk factors specific to that individual. Due to its individualized nature, the predictive accuracy of the anamnestic approach is difficult to examine empirically. The anamnestic approach allows forensic mental health professionals to navigate potential legal concerns over basing risk assessment on predominantly nomothetic data (group-based) as opposed to idiographic data (individual-specific), and it can be a powerful tool when developing treatment plans.

SPJ

SPJ tools use risk-relevant domains similar to the ones included in actuarial assessment tools, but they require the professional using the tool to consider all available information when reaching a decision about an individual's risk level. Rather than relying exclusively on statistics and algorithms, as is done with actuarial risk assessment approaches, SPJ tools permit the clinician to exercise some discretion or judgment in deriving a risk estimate. Studies suggest that this additional component—allowing the professional to use some clinical judgment when estimating risk—provides greater flexibility and allows for the consideration of situational factors relevant to risk prediction. While actuarial assessment tools have been criticized for not allowing individualized consideration, SPJ tools allow for individual consideration; research suggests this is a necessary component in risk assessment. An example of an SPJ tool is the Historical-Clinical-Risk Management-20, which is a 20-item checklist of relevant historical risk factors (e.g., history of unemployment), clinical risk factors (e.g., current symptoms of serious mental illness), and risk management risk factors (e.g., noncompliance with intervention) that are associated with future criminal offending.

Risk Assessment and Risk Management: The Risk- Need-Responsivity (RNR) Framework

The advent of the RNR framework was a significant development for risk prediction and management. The RNR framework focuses not

only on the identification of an individual's risk factors for future criminal behavior but also on identifying and implementing targeted interventions to help mitigate this risk. The RNR framework is predicated on three principles. The *risk* principle states that the level of service provided to an individual should be commensurate with that of individual's risk level—the higher the risk level, the greater the intensity and duration of the interventions. The *need* principle focuses on identifying an individual's dynamic risk factors for antisocial behavior, which are referred to as *criminogenic needs*, and then tailoring risk-reducing interventions to address those needs. The *responsivity* principle focuses on maximizing the benefits an individual derives from an intervention by matching the intervention to a particular offender's characteristics, including learning style, ability level, and motivation.

The RNR framework posits the existence of eight major risk domains: criminal history, education/employment, family/marital, leisure/recreation, companions, drug/alcohol, procriminal attitudes, and antisocial pattern. All of these risk domains have considerable empirical support in terms of being associated with and predictive of future offending behavior. The RNR framework designates individuals as being at higher risk of criminal activity when they have committed previous criminal offenses or exhibited antisocial behavior while under court supervision, have poor employment prospects and a poor employment history, do not enjoy strong support from family members, make poor use of leisure time, associate with antisocial individuals or do not associate with prosocial individuals, exhibit significant past or current problems with substance use, hold attitudes supportive of criminal or antisocial behavior, and have exhibited a pattern of antisocial behavior across their lifetime. An individual's risk level can be reduced by targeting criminogenic needs through appropriate interventions (with the exception of criminal history, which is a static risk factor). Such interventions may include educational and vocational training, strengthening family relationships, engaging in organized and prosocial activities, discontinuing association with negative peers and expansion of a prosocial peer network, desisting from substance use, deconstructing

criminal attitudes and encouraging prosocial thinking, and the development of anger management and problem-solving skills.

Concluding Thoughts

Criminal risk assessment is concerned with predicting and managing an individual's risk of future criminal behavior. This is accomplished by identifying and weighing risk and protective factors related to antisocial behavior. Despite being a relatively new field of study, criminal risk assessment has evolved substantially over the years. At its inception, criminal risk assessment was based almost exclusively on clinical judgment, which often resulted in inaccurate risk predictions. However, the creation and utilization of the actuarial and SPJ approaches to risk assessment have substantially improved the ability of forensic mental health professionals to accurately predict an individual's risk of future criminal behavior. Also, criminal risk assessment is no longer exclusively focused on predicting the likelihood that an individual will engage in future criminal behavior; the current focus is 2-fold and includes assessing the likelihood of future criminal behavior and informing interventions that can be used to reduce an individual's risk level. This dual focus is exemplified by the RNR framework, which has considerable empirical support. The RNR model yields an estimate of an individual's risk level based on the identification of risk factors, and it also can be used to inform interventions that may reduce an offender's risk by addressing criminogenic needs (dynamic risk factors) and promoting protective factors.

CRIMINAL RISK ASSESSMENT, GENERATIONS OF

Offender risk assessment is the foundation of many interventions in the criminal justice system that affects public safety and the offender's liberty. The risk of crime that the offender presents influences arrest and sentencing decisions, parole release, how closely the offender is supervised in the community or in prison, and even who receives treatment and what kind of treatment. Treatment within the criminal justice context has the goal of reducing recidivism, and it may or may not involve mental health treatment depending on its link to criminal behavior. There are different approaches to assessing offender risk, and they have been described as generations of risk assessment, ranging from assessments that are the least valid to assessments that are more predictive of criminal behavior and more useful for managing offenders. The four generations are summarized and their key features are highlighted. The entry ends with some emerging issues and an observation of what may soon form fifth-generation assessments.

First Generation: Professional Judgment

First-generation assessment involves a professional who makes a judgment as to the offender's risk to reoffend and the type of treatment required to reduce the risk. Information about the offender

is typically gathered through interviews with the offender, file reviews, and perhaps interviews with people who know the offender. The important characteristic of first generation risk assessment is that the information is collected in an unstructured manner. Although the professional may gather some information that is common to all offenders, the interviewer may deviate and seek information that may be specific to the offender and his or her situation and influenced by the professional's own training and experience. For example, a psychologist may administer some psychological tests, but the tests chosen are guided by the psychologist's experience and expertise with particular tests. After collating the information, the professional arrives at a judgment regarding the offender's risk to the public and the treatment that the offender requires. In other words, this first generation, professional/clinical approach is highly subjective and dependent upon the professional's training and experience.

Research shows that compared to more structured, empirically validated risk instruments, professional judgments of risk perform no better than chance. One problem with this approach is that using informal, unobservable criteria for making decisions makes it difficult to replicate. For example, clinical experts often disagree on what are the critical factors in a case and, therefore, reach differing judgments on offender risk. Another problem is that the professional may attend to offender characteristics that are unrelated to criminal behavior and ignore the factors that are related to criminal behavior. Because of the poor predictive accuracy of first-generation assessments, this approach has largely been abandoned in favor of second- to fourth-generation assessments.

Second Generation: Actuarial, Static Risk Assessment

Second-generation assessments are actuarial in that the factors assessed are empirically predictive of future criminal behavior. One of the earliest second-generation risk assessment (1928) consisted of 21 items to predict parole failure. Items included factors common to today's instruments (e.g., drug addiction, prior criminal record) and items that are strange by today's standards (e.g., hobo, ne'er-do-well). In second-generation risk

scales, items are typically assigned a score of 0 for its absence or 1 for its presence. This is called the *Burgess method*. Another scoring method uses various statistical methods to assign weights to the item. For example, drug addiction may receive a score of 5 and unemployment a score of 2, reflecting the importance of the specific risk factor. Neither scoring approach has demonstrated superiority. Thus, the Burgess 0–1 scoring method is more common because of its ease of use. Essentially, as scores increase then the likelihood of recidivism increases.

Second-generation risk instruments predict criminal outcomes reasonably well and as well as third- and fourth-generation instruments. However, because they consist almost entirely of static historical items, these instruments fail to accommodate offender change and have little use in case planning and risk reduction. For example, someone who scores high on a second-generation assessment early in life will remain high-risk years later even if the person has adopted a prosocial lifestyle and has stopped all criminal activity. The offender who improves his or her life receives little credit for his or her effort. In addition, these assessments do not tell the criminal justice professional what can be done to reduce the offender's level of risk.

Third Generation: Risk/Need Scales

Second-generation risk scales are used for security, release, and supervision decisions, but the public also expects the criminal justice system to lower the offender's risk and to reintegrate offenders into society. The lack of risk reduction utility in second-generation assessments is overcome with the introduction of dynamic, changeable risk factors referred to as *criminogenic needs*. The third-generation risk instruments are known as *risk/need scales*.

Criminogenic needs are offender needs that are associated with criminal behavior. Examples are substance abuse, procriminal attitudes, and employment problems. Offenders also have non-criminogenic needs (e.g., poor self-esteem, vague feelings of emotional discomfort). The third-generation offender assessments include both static criminal history items and criminogenic need factors. What further distinguishes third-generation assessments from second-generation assessments is that the majority of the items in

third-generation offender instruments consist of dynamic, criminogenic need items.

The most widely used risk/need instrument is the Level of Service Inventory–Revised (LSI-R). Approximately two thirds of the 54 items are dynamic and organized into subcomponents that measure many of the major criminogenic needs of offenders (e.g., education/employment, companions, family/marital). The scoring of the LSI-R uses the Burgess 0–1 method. One of the advantages of the LSI-R, as with all third generation risk assessments, is that it can be used to formulate an offender management plan. By identifying the offender's criminogenic needs (high scores on the subcomponent), the supervising staff can target reductions in the criminogenic needs and achieve an overall reduction in recidivism. Another advantage is that reassessments can be used to monitor offender changes over time and lead to readjustments in the case plan.

Fourth Generation: Risk/Need Case Management

As just noted, a major feature of third-generation assessments over second-generation instruments is that they offer the promise of guiding offender case management. However, there are a few studies showing that despite administering a risk/need instrument staff fail to use the assessment findings in case planning. More often than not, case plans have not incorporated strategies for addressing the offender's criminogenic needs. Consequently, when staff behavior is directly observed (e.g., via audio recordings or video tapes), researchers have found staff failing to focus on the criminogenic needs identified by the assessment.

Recognizing the disconnect between administering a validated risk/need instrument and actually using the findings in the day-to-day supervision of offenders has led to the development of a more structured way of linking the assessment and the case management plan. The best validated fourth-generation instrument is the Level of Service/Case Management Inventory (LS/CMI). The LS/CMI evolved from the LSI-R and has added features to better align the instrument to the Risk-Need-Responsivity model of offender classification and treatment. For this reason, the LS/CMI will serve as an illustration of fourth-generation assessment instruments.

The LS/CMI has a number of sections with the first section basically reflecting the LSI-R but reconfigured to represent the eight major risk/need factors. Section 1 of the LS/CMI provides the overall offender risk score. Section 2 has 21 items that have the potential of being criminogenic for a particular offender (e.g., sexual offense with a child victim, stalking behavior). Section 2 does not produce a total score for risk classification. It is intended to ensure that the test administrator has a comprehensive assessment and does not miss aspects of the offender and his or her situation that could affect supervision. Section 5 assesses responsivity factors. Responsivity refers to individual characteristics that may influence how correctional staff engages the offender during supervision and treatment. For example, supervising an offender with a mental disorder would require a different strategy compared to an offender with no mental disorder. The assessment of responsivity factors is relatively cursory with only 10 items (e.g., poor motivation, low intelligence).

The most important feature of the LS/CMI, and what makes it truly a fourth-generation instrument, is the integration of the assessment with case management. In Section 9, the test administrator rank orders the criminogenic needs of the offender, sets treatment targets, and outlines the steps and interventions needed to reach these goals. This is the case management plan. Section 10 records progress and documents whether the goals are reached (the remaining sections focus on the prison experience and other noncriminogenic factors that may influence treatment and supervision). Furthermore, all of the information from risk/need assessment to case planning and monitoring are presented in one booklet. This is done to ensure that staff focuses their activity on addressing the offender's risk and needs in a structured manner. In summary, fourth-generation offender assessment includes a comprehensive sampling of offender risk, needs, and responsivity factors along with the integration of these factors into a case management plan.

Outstanding Issues and Future Directions

Although second-generation risk assessments predict recidivism, they lack the advantages of the later risk/need instruments. One would expect that

second-generation instruments would have been replaced with the newer instruments, but they remain in widespread use. The reasons for their continued use are 2-fold. First, because second-generation scales have fewer items than third- and fourth-generation risk scales they are easier to use, more efficient, and less costly. However, second-generation instruments fail to assess criminogenic needs. This failure then relates to the second reason for the continued use of the static risk scales: the belief that offenders cannot be rehabilitated. If one accepts this view or the view that it is not the business of corrections to *correct* except through the application of punishment, then third- and fourth-generation assessments add little value.

Another issue is the increasing popularity of what is called *structured professional judgment* (SPJ). SPJ instruments such as the Historical-Clinical-Risk Management-20 structure the factors to be considered but do not link actuarially scores to outcomes. For example, a test administrator may be given guidelines to evaluate substance abuse problems; relationship instability; and attitudes in terms of low, medium, or high risk, but there is no scoring of items or adding them to produce a total score that is associated with a probability of recidivism. SPJ has elements of first-generation (clinical judgment), second-generation (structure), and third-generation (criminogenic needs) assessments. The research on the predictive validity of SPJ has found SPJ to perform better than first-generation professional judgment. However, one review has found it to not predict as well as actuarial assessments for sex offenders. Other reviews of SPJ have mostly focused on the Historical-Clinical-Risk Management-20 where the effect size estimates have ranged from moderate to high. The reason why the Historical-Clinical-Risk Management-20 and its variants may do reasonably well in predicting recidivism is that those completing the instrument have a high level of professional expertise in assessment technologies to begin with and thus are more committed to the assessment process. The SPJ instruments are highly appealing to psychologists, psychiatrists, and other forensic workers because they fit well with a professional training that highly values clinical decision-making.

Related to the continued use of professional judgment is the issue of *professional override* in third- and fourth-generation risk assessments. A

professional override alters the risk level calculated by the instrument. Sometimes a professional override is dictated by policy (e.g., all sex offenders are considered high risk even if they score low risk), or the test administrator is given personal discretion to override the test results. The third- and fourth-generation instruments that have an override feature advise to use the override sparingly and with justification. However, research on the application of overrides has found that they are excessively used and that they increase prediction error.

Progress in offender assessment will continue and, just as each successive generation of offender assessment is replaced by more comprehensive and useful assessment instruments, fourth-generation assessments will eventually lead to a fifth generation. What exactly will fifth-generation instruments look like is difficult to predict. Two possibilities exist. First, there may be an insertion of acute, fast-changing dynamic risk factors such as the sudden loss of employment or intoxication into fourth-generation assessment instruments. Second, considerable research has accrued on the neurophysiological correlates of criminal behavior, particularly violent behavior. The results from these studies could also be added to the present risk/need tool kit. The important lesson is that offender assessment development must be guided by empirical research.

CRIMINAL RISK ASSESSMENT, JUVENILE OFFENDING

Evaluating risk of reoffending for a young person who has come into conflict with the law serves several important functions. At the most basic level, a risk assessment can inform judicial decisions such as whether the youth can be released to community under supervision while awaiting a court date or if the youth should be detained in custody. Similarly, risk assessments can help inform sentencing after a young person has been convicted of a crime; for instance, high-risk youth committing more serious crimes may receive a longer sentence or perhaps a period of custody in a secure youth institution, while lower risk youth may be candidates for a community-based sentence. Perhaps most importantly, a risk assessment can identify those areas in which a young person may need the most help, the dosage of treatment required, and the level of supervision and monitoring in the community. Ultimately, the goal of risk assessment with juvenile offenders should be to inform strategies to prevent recidivism (reoffending) and thus to prevent the young person from becoming an adult offender.

With this primary goal, criminal risk assessments should be organized around the principles of risk, need, and responsivity. Briefly, a risk assessment should assess likelihood of recidivism in terms of assigning risk level, which then informs the intensity of risk management services; for instance, high-risk youth receive high-intensity treatment and supervision, while lower risk youth would require fewer services (risk principle).

Moreover, it is important that risk assessments identify risk factors linked to criminal behavior that have the potential to change, known as *dynamic risk factors* or *criminogenic needs*; these areas can be prioritized for risk management interventions to lower or reduce risk (need principle). Finally, risk assessments should identify unique characteristics in the youth (e.g., motivation, learning style, cultural heritage) that can impact response to risk management (responsivity principle).

The assessment of risk for reoffending in young people who come into contact with the law brings with it many challenges and responsibilities. This entry reviews considerations unique to the assessment of youth and provides a brief overview of structured tools and recommended practices. A comprehensive risk assessment can be used to assess risk to inform the intensity of services (risk principle), identify areas to intervene linked to risk (need principle), and special considerations to adapt services to promote youth engagement (responsivity principle) to help prevent juvenile offenders from entering the adult justice system.

Factors Unique to Juvenile Offender Populations

The terms *youth* or *juvenile* typically refer to the developmental stage of adolescence and, specifically, to someone who is under the age of majority (18 years in Canada and the United States) but who may have begun the physical, social, and emotional process of maturation. The minimum age of criminal responsibility varies from one country to the next. For example, in the United States, most states do not have a minimum age with which a young person can be charged with a crime while the remainder (13 states) range from 6 to 12 years. In the United Kingdom, the minimum age of criminal responsibility ranges from 8 (Scotland) to 10 (England and Wales) years; in Canada, the age is 12 years; and in most European countries, the ages range from 12 to 15 years.

There are several factors that make juvenile offenders different from adult offenders. First, one important consideration is neurological development; for instance, development of the prefrontal cortex, which is responsible for planning, decision-making, ethical reasoning, monitoring,

and inhibiting behavior, continues until the mid-20s and thus is not fully developed in youth. Second and relatedly, young people have greater difficulty controlling strong emotions and the behaviors associated with those emotions. They may act out impulsively without adequately considering the consequences and have a sense of invulnerability. With time, youth develop greater behavioral and emotional control and become increasingly socially and emotionally mature.

Third, since youth tend to live at home with their parents or other caregivers, the family plays a critical role. The parents are responsible for supervision, monitoring behavior, serving as role models, and providing consequences for misbehavior; when this system falls short on any of the aforementioned areas, or condones criminal behavior, the youth is placed at increasing risk for contact with the law. Fourth, the peer system is extremely influential in the life of an adolescent. The opinions and impressions of one's peer group (e.g., attitudes toward criminal behavior) often rival those of the parents; negative peers are thus a potent risk factor for juvenile offending. Finally, the school system is also an important socializing agent, providing opportunities for structured pro-social activity, to learn life skills, and to develop positive relationships.

A Brief Overview of Youth Risk Instruments

Youth risk instruments tend to be downward extensions of the adult tools in which the item content is modified to reflect developmental considerations unique to adolescence. This practice reflects the fact that there are a number of risk factors for reoffending that are common to both youth and adults; however, youth are not mini-adults and differ in important ways as discussed earlier, which needs to be taken into consideration. For instance, special consideration may be given to items that concern school functioning (e.g., poor achievement, disruptive conduct) or parental relationships (e.g., lack of parental monitoring, volatile relations with one or more caregivers). Several risk assessment instruments have been developed to evaluate risk for reoffending in juvenile offenders. These measures tend to be clinical rating scales that are completed by

trained justice system professionals (e.g., psychologists, youth probation officers, or treatment service providers). Such scales are a collection of markers shown by theory or research to predict reoffending (e.g., criminal history, negative peer group), usually organized in the form of a checklist of items that can be rated as present or absent or by degree of seriousness. Such checklists are usually a combination of static or stable (generally, historical unchanging) and dynamic (able to change, such as one's peer group or attitudes) items. Scores on constituent items may be summed to yield a total score that often corresponds to risk levels of differing severity, usually a variation of low, medium, or high; there may be a specific cut-off, or depending on the scale, the assessor may derive a risk level through analysis of the pattern or configuration of items.

Some examples of well-known youth risk tools include the Youth Level of Service/Case Management Inventory, Structured Assessment of Violence Risk for Youth (SAVRY), and the Violence Risk Scale–Youth Version. There is also a clinical checklist of problematic personal, emotional, and behavioral characteristics associated with antisocial behavior known as the *Psychopathy Checklist: Youth Version*, which is commonly used in juvenile risk assessment, although it was not developed to assess risk but rather features associated with psychopathy, so it is not a risk assessment tool per se. There is also a class of tools designed to assess risk for sexual reoffending among youths who have come in contact with the law for sexually intrusive behaviors (e.g., sexual assault of a younger child or peer, inappropriate sexual touching). Some examples of these include the Estimate of Risk for Adolescent Sexual Offense Recidivism and the Juvenile Sexual Offender Assessment Protocol–Second Version.

So, how do we know if these risk measures accurately assess risk? How do we know if youth who are actually at the greatest risk to reoffend are accurately identified by these assessments? These questions all pertain to a particularly important property of youth risk instruments (and risk instruments in general) referred to as *predictive accuracy*; that is, higher scores or higher risk ratings of the tool, indicating a more serious collection of risk factors and greater likelihood of reoffending, are associated with increased rates of reoffending.

There are a number of statistics used to evaluate predictive accuracy; some examples include the correlation coefficient and the area under the curve (AUC). Correlations range in value from -1.0 to $+1.0$; the higher the number, the stronger the association. Positive correlations indicate that increasing scores on the youth tool are associated with higher rates of reoffending. In the risk assessment field, one set of guidelines proposed that correlations of .10 be considered low or small, .24 moderate/medium, and .37 or greater large or high. The AUC statistic ranges from 0 to 1.0 with higher values indicating more accurate ability to discriminate recidivists from nonrecidivists; for instance, an AUC value of .70 indicates that there is a 70% chance that a random recidivist has a higher score on a risk tool than a randomly selected nonrecidivist. The interpretation guidelines mentioned earlier characterize AUC values of .56 to be low/small, .64 medium/moderate, and .71 or greater to be large or high.

With all of this said, a quantitative review of 49 youth recidivism studies that featured the SAVRY, Youth Level of Service/Case Management Inventory (and other variations of this tool), and Psychopathy Checklist: Youth Version found that each tool predicted reoffending with moderate- to high-predictive accuracy. No single instrument was superior to the others in the prediction of recidivism, whether this was violent recidivism or general (i.e., any criminal behavior) recidivism. A further quantitative review of youth sexual offending risk instruments also found that tools such as the Estimate of Risk for Adolescent Sexual Offense Recidivism and Juvenile Sexual Offender Assessment Protocol second version had moderate-predictive accuracy for youth sexual offending.

Considerations in Selecting a Youth Risk Instrument

If the major youth risk instruments seem to predict recidivism equally well, how do we decide on which one to use? There are several factors to consider. First, there needs to be evidence that the instrument can predict the outcome of interest with at least reasonable accuracy, and thus validation research on youth samples, preferably with replication, is needed. When this has been achieved, a primary consideration becomes the general

purpose of the risk assessment. For instance, if the goal of the assessment is to assess risk for general recidivism, the Youth Level of Service/Case Management Inventory may be particularly appropriate; if the outcome is future violence, then the SAVRY or Violence Risk Scale–Youth Version might be appropriate; or if the young person happens to have committed a sexual offense, then the Juvenile Sexual Offender Assessment Protocol–Second Version or Estimate of Risk for Adolescent Sexual Offense Recidivism would be appropriate. Oftentimes, multiple instruments may be used (e.g., a general and a specific measure).

A further consideration is to remember the primary purpose of risk assessment: It is not about predicting whether or not a youth will reoffend in a certain way. Rather, risk assessment should be used to inform the nature and intensity of efforts that need to be taken to manage the youth's risk so that the youth can be helped not to reoffend. What this means is youth with high scores should have more treatment, closer supervision in the community, stricter conditions (e.g., curfew) to help promote compliance, and engagement with multiple systems (e.g., supports for the school, family, and broader community) to help them remain offense-free if possible. Tools with dynamic factors can be critical in identifying problem areas that youth need to change, how much treatment they require, and what types of interventions to use.

Finally, all youths have positive qualities and assets to build, and it is important, wherever possible, to identify these and draw upon them in an effort to manage risk. Some of the tools mentioned earlier take strengths or protective factors into consideration (e.g., SAVRY). There are also special tools designed to assess protective factors directly such as the Structured Assessment of Protective Factors: Youth Version. Other tools such as the Psychopathy Checklist: Youth Version can be helpful in identifying special responsivity issues with which youth may present (e.g., tendency toward manipulation, lacking empathy) and can alert service providers to modify their treatment as needed to maximize gain.

CRIMINAL RISK ASSESSMENT, PSYCHOPATHY

Predicting violence and criminal behavior is a particularly challenging endeavor for the criminal justice system and forensic mental health clinicians alike. Psychopathy, which is sometimes referred to as the *psychopathic personality*, is a psychological construct that has been extensively examined with respect to its utility to predict violence and crime. Psychopathy is a personality disorder characterized by a set of maladaptive traits that impact emotional and interpersonal functioning and behavior. These traits can include callousness and lack of empathy, interpersonal antagonism, fearlessness and lack of anxiety, impulsivity, irresponsibility, and criminal and aggressive behavior (among others). These traits, collectively labeled psychopathy, appear to have significant implications in the criminal justice system. Research has repeatedly shown that mock juries rate individuals described as psychopathic as much more dangerous. Consequently, the use of the term *psychopath* or *psychopathy* carries significant weight in how an offender is viewed by the criminal justice

system with respect to sentencing and amenability for treatment interventions. Interestingly, the construct has been argued by both prosecuting and defense attorneys as an aggravating and mitigating factor for the court to consider prior to sentencing. Prosecutors have argued that criminal defendants labeled psychopaths, or exhibiting strong psychopathic traits, pose a danger to society and therefore should be subjected to longer and harsher sentences (including ineligibility for parole and the death penalty). Conversely, defense attorneys have pointed to the intractable nature of psychopathy as a neurologically based disorder outside the control of the offender.

Assessment of Psychopathy

Several assessment tools have been developed to assess psychopathy. The most popular and widely studied assessment instrument is the Psychopathy Checklist–Revised (PCL-R), developed by Canadian psychologist Robert Hare. Originally developed in the 1980s, the PCL-R was published in 1991 and has been the subject of extensive scientific evaluation. The PCL-R is a clinician rating consisting of 20 characteristics related to the construct of psychopathy. Ratings for these characteristics are assigned with information gathered during a semistructured interview with the individual and a review of records. Scores on the PCL-R have been examined in a number of ways, including a total score as a reflection of global level of psychopathic traits as well as various factor analyses that have predominately focused on interpersonal and affective traits (e.g., callousness, manipulateness, superficial charm, deceitfulness) as a marker of *primary psychopathy* and behavioral and social deviance as the *secondary psychopathy* (e.g., poor behavioral controls, criminal behaviors, history of juvenile delinquency). Hare and his colleagues developed a self-report variant of the PCL-R called the *Self-Report Psychopathy Scale* (SRP), its fourth edition (SRP-4) published in 2016. The SRP-4 has the same underlying structure as the PCL-R.

Another widely researched assessment measure, the Psychopathic Personality Inventory (PPI), was developed by Scott Lilienfeld. Like the SRP-4, the PPI is a self-report instrument that assesses underlying traits of psychopathy, such as rebellious

nonconformity, fearlessness, stress immunity, and blame externalization (among others). The PPI has been examined in correctional, community, and university settings. The eight primary scales of the PPI have been examined through factor analyses, wherein three factors emerge: Fearless Dominance, Self-Centered Impulsivity, and Coldheartedness. *Fearless Dominance* reflects a tendency to remain calm in intense (and potentially dangerous) situations, a bold interpersonal style, and increased ability to recover from stress and anxiety. *Self-Centered Impulsivity* captures tendencies to act in a rebellious, impulsive manner without regard for social standards. *Coldheartedness*, as the term implies, is linked to deficiencies in empathy and interpersonal affiliation. It should be noted that there are other self-report measures of psychopathy aside from the tools already mentioned, such as the Levenson SRP, the Triarchic Psychopathy Measure, and the Dark Triad measure. These measures are primarily used in research and generally have not been utilized in forensic psychological evaluations aimed at assessing risk for violence and criminal behavior. The SRP and PPI are commercially available for psychologists to use in psychological evaluations, which make them more admissible in court and much more likely to be utilized in forensic mental health assessments.

Risk Assessment

Predicting future behavior is a difficult task, given the complex interplay between internal (e.g., personality, cognitive abilities) and situational factors. When the target of prediction is violence and criminal behavior, the task becomes even more challenging, given the consequences for both false positives (e.g., restrictions on personal freedoms and liberties) and false negatives (e.g., future victims of violence). The fields of forensic psychology and psychiatry have identified a number of factors that are empirically associated with future criminal and violent behavior. Many of these factors are historical in nature and include things such as a history of violence, antisocial and criminal behaviors, severe mental illness, substance abuse, and previous poor outcomes while under community supervision (e.g., rearrested while on probation or parole). Forensic mental health evaluations that

target risk for violence and criminal behavior often assess these factors. Psychological factors are also considered, such as a history of maladaptive functioning and current symptoms of mental illness, including personality psychopathology. Along these lines, many psychological evaluations aimed at predicting risk for criminal behavior and violence include an assessment of psychopathic traits. Whether considered globally (i.e., overall degree of psychopathy displayed by the individual) or as underlying constituent traits associated with psychopathy (e.g., callousness, impulsivity, irresponsibility), assessment of psychopathy is often a central component of a criminal risk evaluation. There is much debate in the field of psychology about what exactly constitutes the construct of psychopathy. The field has generally moved away from considering psychopathy as a homogeneous construct, instead focusing on various factors of psychopathy as well as the underlying traits that make up this disorder. For instance, some operationalizations of psychopathy emphasize antagonism and lack of conscientiousness (i.e., disinhibition), whereas others also include a focus on a bold and fearless temperament.

Research examining the utility of psychopathy as a predictor of violence and criminal behavior has generally focused on three questions:

1. To what extent is psychopathy predictive of violence and crime?
2. Are specific facets or traits of psychopathy particularly predictive of violence and crime?
3. How do psychopathy measures (e.g., PCL-R, PPI-Revised) compare to other violence risk measures in the prediction of violence?

Is Psychopathy Predictive of Violence and Crime?

Regarding the first point, a number of empirical studies have directly examined the ability of psychopathy, often conceptualized with the PCL-R (and to some extent, the PPI), to predict violence and criminal behavior. Research clearly shows that the PCL-R is at least moderately linked with violence, criminal recidivism (reoffending), and institutional behavioral problems for incarcerated offenders and forensic psychiatric patients. One of

the most extensive examinations of violence risk assessment was the MacArthur Study of Mental Disorder and Violence by John Monahan and colleagues. They captured the construct of psychopathy with a Screening Version of the PCL and found that it was a robust predictor of violence among forensic inpatients who had been discharged back into the community, even after controlling for other various risk factors. Given the vast amount of research that has examined the relationship between psychopathy and various antisocial outcomes (e.g., crime, violence), meta-analytic reviews are helpful to consider in summarizing the findings from various studies. Anne-Marie Leistico, Randall Salekin, Jamie DeCoster, and Richard Rogers completed a meta-analytic review of 95 studies investigating the PCL in relation to antisocial behavior. They found that the total score of the PCL-R was a significant predictor of violence and antisocial behavior.

However, the PCL-R has been the subject of controversy with respect to its use in risk assessments. All psychological tests and measures are subject to psychometric evaluation, which generally involves examination of the test's reliability and validity. In this respect, the PCL-R is generally considered to be a reliable instrument and one that has amassed an incredible amount of validation. However, one particular form of reliability, known as *field reliability*, is focused on examining how reliable the instrument is *outside the lab* when it is used in the field, such as for forensic mental health assessments. Specifically, this form of reliability assesses whether a test is reliable in the hands of clinicians in various clinical circumstances rather than in the strictly controlled nature of the lab, where most validation research is conducted. The issue of field reliability became a focus of the PCL-R in a series of studies by Marcus Boccaccini, Daniel Murrie, and John Edens (and others), who examined the use of the measure in various types of risk assessments. Boccaccini and Murrie and their colleagues examined sexual offender risk evaluations in Texas, which provides a unique opportunity to evaluate field reliability since the state of Texas required that every convicted sexual offender's risk for recidivism (which includes the PCL-R) be evaluated by a forensic expert retained by the state and one retained by the defense. They found that

differences between state-appointed experts (who generally reported higher PCL-R scores) and defense-appointed experts (who generally reported lower PCL-R scores) for the same defendant exceeded what would be expected based on the reliability of the measure (the standard error of measurement). These authors examined their findings within the framework of a particular bias called *adversarial allegiance*, which implies that an evaluator may be biased to form an opinion in line with the side that retained the expert. Thus, defense-retained experts may be more likely to report lower levels of psychopathy, and prosecution-retained experts may be more likely to find higher levels of psychopathy. Contrary to these findings, a number of studies in Canada suggest that the field reliability of the PCL-R is good in Canadian criminal proceedings.

Regardless of its underlying cause (e.g., adversarial allegiance), the issue of field reliability is gaining a lot of attention in the research literature and continues to be an important topic in risk assessment. It should be noted that the issue of field reliability and adversarial allegiance are not unique to the PCL-R and psychopathy and has been examined in other forensic instruments (e.g., Static-99) and contexts (e.g., sexual offender evaluations). Researchers examining the utility of the PCL-R in forensic mental health assessment of violence risk have suggested that forensic examiners obtain certifications of their competency before completing assessments for the courts. Moreover, forensic examiners should be mindful of the reliability of their findings and note this for the court to consider in light of a risk assessment.

For a variety of practical reasons, self-report measures of psychopathy are increasingly being used in forensic mental health evaluations. While there is not as much research examining the utility of self-report measures in predicting violence and criminal behavior (in comparison to the PCL-R), there are some preliminary findings that suggest they may have utility in this area. Michael Vitacco, Craig Neumann, and Dustin Pardini examined an earlier version of the SRP (SRP-III) in a moderately sized sample of community-residing males. Utilizing official criminal records, criminal offending was assessed on an average of 3.5 years after the SRP-III was administered. Scores on the

SRP-III were able to predict charges for violent and serious criminal charges, even after controlling for other risk factors for violence and antisocial behavior.

Are Particular Facets or Traits of Psychopathy Particularly Predictive of Violence?

Research has shown that most of the predictive ability of psychopathy measures, such as the PCL-R and PPI, are due to their components that capture behavioral deviance and antisocial behavior. On the PCL-R, the second factor, labeled *Social Deviance*, comprises items that assess a history of poor behavioral control, criminal versatility (i.e., how many types of criminal activities engaged in by the offender), juvenile delinquency, and poor outcomes when previously placed on community control (e.g., probation). This factor of the PCL-R largely accounts for a history of externalizing behavior. The PCL-R meta-analysis mentioned earlier found that the social deviance component of psychopathy (i.e., Factor 2) was a stronger predictor of antisocial behavior for psychiatric inpatients than incarcerated offenders, whereas the interpersonal and affective components of psychopathy (i.e., Factor 1) were stronger predictors of antisocial conduct in samples containing a higher percentage of females. Factor 2 scores on the PCL-R were also better at predicting antisocial conduct at longer follow-up periods.

Studies examining the PPI in relation to the prediction of violence have generally found that *Self-Centered Impulsivity*, the factor of the PPI that captures an individual's tendency to act impulsively without consideration of others, accounts for most of the predictive capacity of the measure to predict violence. Edens and Barbara McDermott, for example, found that scores on the PPI Self-Centered Impulsivity scale were significantly associated with two measures of violence risk in a sample of forensic inpatients: the Violence Risk Appraisal Guide and the Historical-Clinical-Risk Management-20. Other research has found that PPI Self-Centered Impulsivity was significantly related to numerous markers of antisocial behaviors, including domestic violence and drug and alcohol use (among others).

Although some have argued that the bold or fearless dominance component found in the PPI may not be as central to the psychopathy construct as interpersonal antagonism and impulsivity, recent research has found that the former component is associated with criminal recidivism and treatment failure in a sample of domestic violence batterers. This research by Martin Sellbom and his colleagues found that fearless dominance moderated the relationship between poor impulse control and failure of domestic violence treatment. This means that the combination of PPI Fearless Dominance and Self-Centered Impulsivity increased treatment failure. Conceptually, it makes sense that perpetrators of domestic violence who show traits such as boldness and fearless dominance (which is linked to traits such as pathological narcissism) are more likely to reject the idea that they need intervention.

Some studies have found that the presence of primary psychopathic traits, such as callousness and lack of remorse, is related to one's risk for future violence, particularly interpersonal and relational violence and instrumental aggression (i.e., violence directed toward obtaining a goal). For instance, sexual offenders who commit aggressive and violent rapes often exhibit significant primary psychopathic traits. Moreover, these offenders tend to show higher rates of sexual and general recidivism among sexual offenders as a whole.

How Does Psychopathy Compare to Other Violence Risk Measures in the Prediction of Violence?

Psychopathy assessed by the PCL-R and other instruments has been compared with other, violence-specific risk measures in a variety of settings. The results have generally been mixed, with some studies showing equivalent predictive capacity for PCL-R scores and other violence risk instruments. Other studies have shown lower predictive ability for the PCL-R in relation to specific risk assessment instruments. The most comprehensive meta-analytic review of the PCL-R in relation to other risk assessment instruments was completed by Min Yang, Stephen Wong, and Jeremy Coid. These authors found little difference between the PCL-R (particularly

Factor 2) and eight other violence risk measures (e.g., Historical-Clinical-Risk Management-20, Violence Risk Appraisal Guide) in the prediction of violence. Similar to findings discussed earlier, they found that Factor 1 generally did not contribute to the prediction of violence risk, although the authors noted that it may play a role in moderating the risk of sexual violence among moderate- to high-risk sexual offenders.

Psychopathy and Response to Violence Interventions

Criminal risk assessments typically involve consideration of an individual's likelihood for violence and/or recidivism. Frequently, those assessments include consideration of efforts that might be employed by mental health professionals to mitigate, or lower, one's risk. Part of that consideration involves assessing the individual's amenability for intervention. In this respect, the assessment of psychopathy can play an important role. In addition to examining its role as a predictor of violence and risk for criminal behavior, psychopathy is also considered in terms of its impact in treatment settings. Following adjudication in criminal cases, many offenders are referred to mandatory treatment programs. These are most prevalent with respect to domestic violence and batterer's interventions and sexual offender treatment. Consequently, the role that psychopathy plays in relation to treatment and interventions for violence and criminal behavior is important to consider in a risk assessment. Psychopathic traits have the potential to impact the offender's participation in and response to treatment. For example, the interpersonal components of psychopathy (e.g., manipulateness, conning, inflated ego) can interfere with efforts in treatment. Participants in these settings with strong psychopathic traits can manipulate the treatment provider and other members of the group. Indeed, positive impression management through the use of charm, conning, and manipulation can leave treatment providers questioning the need for intervention.

A major component of offender-based interventions (such as batterer's interventions and sexual offender treatment programs) is the development of empathy. Many of these programs focus on

improving offenders' ability to appreciate the impact they have on their victims. Psychopathic traits can interfere with these treatment goals because psychopathic offenders often lack the capacity for moral reasoning and empathy.

Ongoing Role of Psychopathy in Risk Assessment

While the specific role that psychopathy plays in violence risk assessment continues to be debated and studied, it is clear that this construct will remain an important topic in the violence risk literature. Future assessment of psychopathy will include greater contributions from neuroscience and neuroimaging techniques. The criminal justice system will have to find ways to incorporate these types of data and findings in light of the burgeoning neuroscience in the area of psychopathy. Moreover, the criminal justice system will have to contend with adversarial arguments about the aggravating and mitigating nature of psychopathy as a factor to consider in sentencing convicted offenders. Regardless, it is clear that psychopathy will continue to play a significant role in violence risk assessment.

CRIMINAL RISK ASSESSMENT, SEXUAL OFFENDING

Although legal definitions of sexual offenses vary, the term *sexual offending* typically denotes offenses whereby an individual engages in unwanted sexual acts with another person who does not give, or is unable to provide, consent. Given the impact such acts have on survivors, sexual offenses receive considerable attention from the media, policy makers, and the criminal justice system. These concerns highlight the need for accurately assessing the likelihood that those who have offended sexually will recidivate or commit future sexual offenses. After reviewing factors associated with risk of sexual reoffending, this entry describes assessment techniques commonly used by those conducting risk assessments for sexual offending and outlines the components of a sex offender risk assessment.

Factors Associated With Risk of Sexual Reoffending

When conducting sex offender risk assessments, evaluators utilize both static and dynamic risk factors. Static risk factors remain constant or cannot be changed by treatment (e.g., the offender's prior offense history), whereas those factors that may fluctuate are referred to as *dynamic risk factors*. Some dynamic factors may also be referred to as *long-term vulnerabilities* or *risk-relevant propensities* as these factors, while relatively stable, are oftentimes the focus of sex offender treatment programs designed to lessen the offender's overall risk. See Table 1 for a list of static and dynamic risk factors for sexual risk.

One of the most useful predictors of future behavior is previous behavior, and the same is true when predicting risk of sexual reoffense. Offenders who have previously committed sexual offenses are at a greater risk of sexual recidivism compared to those with nonsexual prior offenses. Additionally, the younger one was at the time of his or her first sexual offense, the greater the risk of future sexual offending. The time span of sexual offending is also associated with risk, with offenders who have a longer sexual offending history being

Table 1 Static and Dynamic Sexual Risk Factors

Static Risk Factors	Dynamic Risk Factors
Prior sexual offense	Sexually deviant interests
Young age	Impulsivity
Male victim	Attitudes supportive of sexual assault
Prepubescent victim	Sexual preoccupation
History of substance use	
Prior failure on conditional release	
No prior stable, adult, intimate relationships	
Two or more paraphilic diagnoses	
Psychopathy	

at an increased risk of sexual recidivism. For example, a 30-year-old offender who has been offending sexually since the age of 16 has greater risk of continued offending compared to a 30-year-old offender whose sexual offending history has spanned 5 years.

The offender's current age is also a determinant of risk of sexual recidivism. Adult offenders under the age of 30 typically have the highest rates of sexual reoffense compared to older offenders. Although the risk of sexual recidivism declines with age, those who offend against children tend to have a slower decline in risk of sexual reoffense over time compared to other types of sexual offenders.

An additional dynamic risk factor for sexual recidivism is the presence of deviant sexual interests. There is some debate regarding how to define sexual deviance, but those who display sexual attraction to prepubescent children are often categorized as demonstrating sexually deviant interests and are thus viewed as having a greater risk of sexual recidivism. Additionally, individuals who derive sexual pleasure from torturing or humiliating their victim or prefer sex that includes force or violence to consensual sex are also considered to be demonstrating deviant sexual interests.

Offenders who derive sexual pleasure from torturing or humiliating a nonconsenting individual may meet diagnostic criteria for the paraphilia sexual sadism. Paraphilias involve fantasizing about, or acting on, sexual interests that are generally considered atypical. Individuals diagnosed

with a paraphilia may experience distress or impairment in functioning as a result of their sexual interests. In addition to some paraphilias being reflective of deviant sexual interests, research suggests that offenders diagnosed with two or more paraphilias are at increased risk of reoffending sexually.

Offenders who display attitudes that are supportive of sexual assault, such as the belief that one is entitled to sex, are at an increased risk of sexual offending. Being preoccupied with sex is also associated with an increased risk of sexual offending. Indicators of preoccupation with sex include the belief that one has a stronger sexual drive than others and placing an inflated level of importance on sexual behavior compared to other parts of one's life. How frequently one views pornographic material, engages in sexual behavior, or fanaticizes about sexual acts can also be indicators of sexual preoccupation. Sexual preoccupation may also negatively impact an offender's personal relationships, with research indicating that those who have no current or prior intimate relationships with another adult are at an increased risk of sexual reoffense.

Sexual offenders who display antisocial traits, such as impulsivity and a disregard for social norms, are also at an increased risk of sexual recidivism. Failure to adhere to treatment or supervision requirements is oftentimes indicative of antisocial tendencies, with offenders who leave treatment prematurely or fail to abide by supervisory requirements being at an increased risk of sexual

recidivism. Although the relevance of antisocial tendencies to risk of reoffense is true for sex offenders in general, those who sexually offend against adults are more likely to exhibit antisocial traits than those who offend against children.

Another risk factor for sexual reoffense, psychopathy, is also more prevalent in those who offend against adults versus those who offend against children. Psychopathy constitutes a personality construct that includes interpersonal, emotional, and behavioral traits. Individuals classified as psychopathic may show traits such as lack of remorse or empathy, poor behavioral controls, and sexual promiscuity. In addition to being associated with risk of violent offending, those who are classified as psychopathic are also more likely to engage in sexual recidivism compared to those who are not considered psychopathic. A final risk factor more commonly seen in those who offend against adults is substance use diagnoses, with those who have a history of abusing substances being at a greater risk of sexual recidivism.

Victim demographics are also associated with risk of sexual recidivism. Sexual offenders who offend against males or unrelated victims pose a greater risk of sexual recidivism than those who offend against females or those known to them. Additionally, individuals who offend against various types of victims (e.g., males and females, adolescents and adults) pose a greater threat for reoffense compared to offenders who only offend against a singular type of victim.

Sexual Recidivism Risk Assessment Instruments

Various instruments have been designed to assess the risk of sexual recidivism and provide evaluators with more objective methods of assessing risk of sexual recidivism. Although these measures differ with regard to how risk is conceptualized and measured, a 2009 meta-analysis by R. Karl Hanson and Kelley E. Morton-Bourgon suggested that sex offender risk assessment instruments have similar levels of predictive accuracy. Given findings of similar predictive accuracy across leading measures, the decision regarding which instrument to employ often rests on selecting an approach to estimating sexual recidivism that best fits with the purpose of the evaluation.

For example, evaluators seeking to identify changes in an offender's risk over time may choose a structured professional judgment instrument that includes static and dynamic factors. Structured professional judgments may also include protective factors, or those that reduce an offender's overall risk, and identify relevant risk factors to consider while allowing for professional judgment when making the final risk determination. The Sexual Violence Risk-20 is considered a structured professional judgment and includes 20 items that address the offender's criminal history, psychosocial functioning, and future plans. This instrument allows evaluators to classify the offender's overall risk and prioritize the types of interventions for the offender.

The STATIC-2002R is an example of an actuarial instrument or instrument that arrives at a final risk score and risk estimate based on a mathematical formula. The current version of the instrument contains 14 items that cover information about the offender's age, sexual offending and general criminal history, deviant sexual interests, and victim characteristics. The scores from the individual items are summed to obtain a final score of risk that corresponds to a risk classification level ranging from low to high in likelihood for sexual reoffense over 7 and 10 years. Although this instrument provides long-term recidivism estimates and relies on empirically supported items, some express concern that the instrument does not show changes in risk of sexual reoffense given the sole reliance on static variables.

A final group of risk assessment instruments is referred to as *mechanical instruments* and is similar to actuarials in that instructions are provided for what risk items to consider and how to combine the factors to arrive at a risk estimate. Unlike actuarials, mechanical instruments do not provide information for how the final risk estimates relate to recidivism rates. An example of a mechanical instrument is the Sex Offender Treatment Intervention and Progress Scale, which includes 16 dynamic risk items related to the offender's sexual deviance, general criminal behavior, and interpersonal relationships. Total scores are categorized into three levels of risk, with research suggesting that the instrument is reliable and moderately predicts risk of sexual recidivism.

Additional Assessment Measures

Evaluators may also utilize assessment procedures, such as the penile plethysmograph (PPG), that measure physical responses to stimuli as a strategy to evaluate sexual risk. Although a version is available for use with females, the version designed for use with males has been researched extensively and is the focus of the description that follows. The PPG is administered by having the male place an apparatus on his penis, termed a *circumferential strain gauge*, that measures fluctuations in penile circumference or volume in response to audio or visual sexual stimuli (e.g., narratives, images) that depict male and female adults and children. Fluctuations in penile volume or circumference are purported to be indices of sexual arousal that are associated with sexual recidivism. For example, an offender who displays arousal in response to images of female children can be inferred to be at greater risk of offending against female children than an offender who does not display a pattern of arousal in response to these stimuli.

Although some research suggests that the PPG effectively assesses risk for those who offend against children, there are several concerns regarding the use of the instrument. First, the obvious nature of how the instrument assesses risk can result in offenders distorting their results. Individuals could deliberately imagine stimuli other than the images presented to interfere with the validity of test results. Additionally, research suggests that males can control penile volume so that the presence, or absence, of arousal may be unrelated to the images that the individual is viewing. Because of these concerns, and the intrusiveness of the procedure, evaluators may opt to utilize another physiological measure when assessing sexual risk.

Gene Abel and associates developed the Abel Assessment for Sexual Interest to assess sexual preference. The Abel Assessment requires individuals to first complete a questionnaire regarding deviant sexual interests, sexual history, and criminal history. They then view a series of 160 digital images depicting individuals who are clothed in bathing suits and vary with regard to age, gender, and ethnicity. Offenders are asked to initially view each image and then go through the images a second time to rate their level of sexual arousal in response to each picture. In addition to obtaining

a measure of the individual's reported arousal to each image, the amount of time spent viewing each image is recorded.

The assumption behind the Abel Assessment is that the length of time spent viewing stimuli is indicative of the level of sexual arousal one experiences in response to the images. Although this instrument has been shown to have similar predictive utility as the PPG when detecting those who offend against children, there is concern that without a direct measure of sexual arousal, one cannot assume that the length of interest shown in a type of image is necessarily indicative of sexual arousal.

Conducting the Evaluation

Evaluations of sexual risk often assist in determining an appropriate sentence, whether an offender meets criteria to be labeled as a sexually violent predator, and to inform treatment recommendations or management strategies to prevent continued sexual violence. When evaluating risk of sexual recidivism, evaluators should be aware of the limitations of certain assessment methods and applicability of specific assessment instruments to ensure selecting the best assessment approach for a given evaluation. For example, some assessment procedures (e.g., PPG) work more effectively with those who offend against children and, thus, may be less suitable for evaluating those with no known history of offending against children. Demographic characteristics may also influence which instrument is appropriate as many risk assessment instruments were designed for use with males, which limits their applicability when evaluating risk of a female sexual offender. There is also concern that the more commonly used sex offender risk assessments may not accurately assess risk for offenders who display symptoms of a major mental illness or diagnosis of intellectual disability, and it is important that evaluators convey any limitations to their assessment strategy within their report.

Review of Available Records and Collateral Sources

Records are considered to be the cornerstone of any forensic evaluation and the same is true of evaluations for sexual violence risk. An offender's criminal history, including police reports, should

be obtained as these documents provide information regarding the offender's offense history, prior compliance with supervision requirements, and victims' demographic information. If an offender is currently incarcerated or in a psychiatric facility, records from the facility can assist in determining whether the offender is displaying active mental health symptoms and whether he or she has complied with supervision requirements.

Mental health records are also used to determine the presence of psychiatric diagnoses related to risk of reoffense and whether the offender has complied with, or benefited from, previous attempts to manage mental health symptoms. Evaluators should obtain previous risk assessments, if available, as these records may contain additional information regarding the offender's offending patterns and responsivity to treatment as well as serve as a comparison point to determine any fluctuations in risk of sexual recidivism. Additional records, or collateral sources, may include school records, child protective agency records, interviews with family members, or interviews with previous treatment providers. It is preferable to review records before interviewing the offender as information contained in the records can assist the evaluator select relevant lines of inquiry and provide the necessary knowledge for asking follow-up questions should an offender provide information that contradicts available records.

Interview

The types of questions asked during the interview may depend on the reason for the evaluation. For example, if conducting a sexually violent predator evaluation, the evaluator must address factors outlined in statutes, which influences the degree to which certain areas are covered during an interview. Although the information emphasized during an interview may vary depending on the reason for the evaluation, evaluators typically gather information regarding the offender's background, mental health history, and criminal history. An offender's background can aid in identifying patterns of behavior as well as the onset of mental health diagnoses or substance use. Evaluators question offenders about mental health symptoms to determine whether there is evidence to warrant a mental health diagnosis that has been previously undiagnosed. Questions regarding the offender's sexual offending history and their history of sexual

functioning in general is relevant, as it can provide information about the potential for sexual preoccupation or a preference for nonconsensual sex.

Utility of Standardized Risk Assessment Instruments

Evaluators should utilize a standardized risk assessment instrument, such as those reviewed herein. Although the record review and interview provide important information about the presence of risk factors, a standardized risk assessment instrument provides a more objective evaluation of risk of sexual recidivism and is considered necessary during a risk assessment. There is a large number of instruments available to assess risk of sexual recidivism, and it is important that evaluators weigh relevant factors to determine which instrument is most appropriate for the evaluation.

Future Research

Although significant advances have been made in predicting risk of sexual recidivism, additional research is required to determine whether current practice accurately predicts risk of sexual violence for specific groups (e.g., female sex offenders) and the extent to which available instruments accurately predict risk of sexual recidivism. This research will help ensure that evaluators are conducting evaluations that align with ethical guidelines and standards of practice as well as to maximize the chance predictions of risk of sexual violence are both reliable and accurate.

CRIMINAL RISK ASSESSMENT, STALKING

Stalking can be defined as a pattern of targeted, repeated, and unwanted intrusive acts that can be reasonably expected to cause apprehension, distress, or fear. Stalking victims frequently experience a significant psychological harm, and approximately one third are physically assaulted. Given the damage associated with prolonged or violent stalking, key concerns for criminal justice agencies are accurate assessment and identification of those stalkers most likely to continue to stalk, stalk again in the future, or become physically violent. Risk assessment has therefore been a key focus of stalking research, and two structured risk assessment instruments for stalking now exist. This entry describes the development of the stalking risk assessment literature, identifies challenges when assessing stalking risks, and reviews risk factors that have been empirically linked to stalking recidivism (reoffending) and stalking-related violence.

Stalking Risk Assessment Research

Identifying risk factors that can be used to predict stalking-related violence has been a central goal of stalking research since the field began in the early

1990s. It was such a focus that in 2007 the prominent stalking researcher, Reid Meloy, described it as the *current quest for the Holy Grail*. The stalking risk assessment literature developed as the broader literatures on violence, sexual, and general offending risk assessment were flourishing, influencing how stalking risk assessment was investigated and understood. However, it quickly became apparent that there were characteristics unique to stalking that meant existing risk assessment research and instruments were not appropriate for all stalking cases. It took some years to develop a body of research that could inform the development of structured risk assessment instruments specifically for stalking, with the first instruments published in the late 2000s (the *Guidelines for Stalking Assessment and Management* in 2008 and the *Stalking Risk Profile* in 2009).

Challenges of Assessing Stalking Risk

There are a range of factors that make stalking risk assessment a particular challenge for researchers and practitioners. The first, and most obvious, difficulty is the diversity of both stalking behaviors and the contexts in which stalking arises. Stalking occurs between former intimates, between neighbors, workmates, strangers, and family members. It can be amorous in intent, or vengeful and aggressive, or both. This makes it extremely difficult, if not impossible, to derive the kinds of algorithmic actuarial risk assessment instruments that were successfully developed for violence, sexual offending, and general offending during the 1990s. Even if large enough samples of stalkers could be collected, it would be impossible to identify a single algorithm, or set of risk factors, among the variations in stalkers and their behaviors.

In addition to its diversity, stalking differs from violent, sexual, and general offending in other important ways:

- Stalking is targeted, and the nature of the prior relationship between the victim and the perpetrator plays a central role in the stalking and likely outcomes.
- The majority of stalkers are not physically violent, but can still cause significant harm to the victim through their intrusive and relentless behavior, meaning that stalking risk goes beyond physical violence.

- Stalking involves behaviors that would otherwise be considered nonthreatening and nonviolent, possibly rendering risk factors for physical violence unrelated to future stalking.
- Stalking is by definition persistent with risk toward a specific victim possibly fluctuating over time, even while risk to other people is low.

In their seminal 2002 article, Canadian psychologists Randall Kropp, Stephen Hart, and David Lyon noted that these characteristics were inconsistent with most of the extant literature of violence risk assessment. This literature ignored the relationship between the victim and the perpetrator, examined only the likelihood of physical harm, and followed up discrete outcomes over a relatively limited period. They recommended that given the unique nature of stalking risk, structured professional judgment approaches would be useful and went on to develop the Stalking Assessment and Management with this in mind.

A subsequent 2006 article published by a group of Australian researchers and clinicians elaborated further on these issues. This group of authors suggested that one way of dealing with some of these challenges was to change how stalking risk was conceptualized. Rather than assessing the *risk of stalking* in a particular case, they suggested that it is more useful to think of stalking as a behavior that presents different kinds of risk to the victim, including psychological, social, or physical harm if the stalking continues or recurs and/or escalates to physical or sexual assault. With this framework, each type of outcome could be investigated and specific risk factors identified. This perspective strongly influenced the same authors' subsequent development of the Stalking Risk Profile.

Stalking Risk Assessment Research

There are now dozens of studies examining risk factors for a wide variety of different outcomes in stalking cases. Nevertheless, in comparison with the general violence or sexual offending risk assessment literature, research on stalking risk remains relatively limited, meaning that conclusions must be drawn cautiously. Moreover, the majority of risk factors identified in existing studies are static, or unchangeable, historical characteristics such as *past violence*, which are not

particularly helpful to risk management. Future research examining more nuanced risk factors is needed to better target treatment that can reduce the risk of future stalking or stalking-related violence.

Examining Risk Factors for Future Stalking

Future stalking may involve continued stalking of the current victim (or if the stalking has ceased, recommenced stalking of the same victim) or the risk of future stalking of a different victim. Due to the lack of research, however, the empirical evidence for risk factors for these outcomes is relatively weak.

Unlike research related to stalking risk factors, some information about relevant risk factors can be gleaned from the small body of research examining stalking recidivism. The first study of this kind was published in 2003 and used a sample of 148 U.S. stalkers who were followed up between 2.5 and 12 years after a court assessment, predominantly using criminal justice records. In total, 49% of the same reoffended with further stalking, 80% within a year of the initial assessment. The strongest predictor of stalking recidivism was the presence of a personality disorder, particularly the presence of antisocial, narcissistic, or borderline personality traits. The combination of a personality disorder and substance abuse at the time of the original assessment also contributed significantly to recidivism, as did having a prior intimate relationship with the original victim. Aspects of these findings have been replicated in other studies: Personality disorder or problematic traits were also linked to multiple stalking episodes in two Australian studies (2012 and 2017), each involving a sample of approximately 150 forensically involved stalkers. Other risk factors for future stalking include the nature of the prior relationship between victim and stalker and the perpetrator's criminal history. A large study of over 1,000 stalkers from North America reported that former intimates were more likely to reoffend than those with other kinds of relationships to the index victim. The presence of a criminal history was linked to stalking recidivism in two studies, the first a 2009 Dutch study and the second from Canada in 2011, using quite different forensically involved samples. The Canadian study also identified a

history of mental health diagnosis as a risk factor, although the relationship was weak and requires further investigation.

Only one Australian study (published as a thesis in 2015) has been able to differentiate between risk factors for future stalking of the same versus a different victim. Information from police records of 160 Australian stalkers showed that 28% were charged with further stalking offenses over an average 5.5-year follow-up period. Of these, 56% reoffended against the original victim and 56% against a new victim (6% stalked both the same and a new victim), with significantly shorter time to reoffending involving the same victim (estimated mean time of 40 weeks vs. 108 weeks). When examining any stalking recidivism, personality disorder or problematic traits were again related to recidivism, as was a history of stalking prior to the episode that led to their assessment for the research (the index episode). Duration of the index episode was also linked to subsequent stalking charges, with stalkers who had already persisted for more than 6 months having almost 3 times greater odds of reoffending.

This 2015 Australian study also examined risk factors for reoffending against specific stalking victims, with marked differences in the predictors identified. Stalkers who reoffended against the same victim were significantly more likely to be male, to have problematic personality traits or disorder, an index stalking duration of greater than 6 months, and to have approached the victim during the index stalking episode. In subsequent multivariate models, major mental illness was also shown to be important to predicting this outcome. None of these risk factors were related to reoffending against a different victim. Instead, a history of prior stalking, a criminal history, and being a stranger to the stalking victim were significant predictors. These findings suggest that different risk factors may, in fact, be related to future stalking of the same, versus a different, victim. Further research and replication of these results are required to provide evidence-based risk assessments of future stalking.

Examining Risk Factors for Stalking-Related Violence

In contrast to the limited literature on the risk of future stalking, by 2000, there were more than a

dozen published studies investigating risk factors for physical violence during a stalking episode. A meta-analysis of 13 studies involving 1,159 individuals was published in 2004, with an overall rate of physical violence by stalkers of 38.7%. The presence of threats, substance use by the stalker, the absence of a psychotic disorder, a history of violence, and a prior intimate relationship between victim and stalker were all positively correlated with physical violence during the stalking episode.

These findings were replicated a decade later in an expanded meta-analysis of 25 studies with over 5,000 participants. The overall rate of physical violence in this larger sample was similar, 35%. Strengthening and expanding the findings of the earlier review, the newer analysis identified prior intimate relationship, threats, perpetrator substance use, absence of psychosis in the stalker, and stalker history of violence as risk factors for perpetrating stalking violence. In addition, stalker personality disorder, criminal history, and male gender were identified as risk factors. These meta-analyses provide strong evidence that stalking-related violence is most commonly committed by former intimates who have a broader range of antisocial characteristics and engage in a range of problematic and criminal behaviors in addition to stalking.

Risk factors such as those identified in the meta-analyses, while useful for prediction at the group level, are not always useful for assessing risk in individual cases or designing clinical interventions to reduce risk. Stranger and acquaintance stalkers are occasionally violent, as are psychotic stalkers, making risk assessment a nuanced and challenging task. The two structured risk assessment instruments developed to assess the risk of stalking-related violence attempt to assist with this process. They both include a range of other, more dynamic, risk factors such as the presence and intensity of anger toward the victim, irrationality or distress on the part of the stalker, and consideration of the pattern of stalking behavior. While they are drawn from the broader stalking and violence risk assessment literatures, the empirical relationship of these risk factors to stalking violence is yet to be specifically evaluated and should be the focus of future research.

CRIMINAL RISK ASSESSMENT, STRUCTURED PROFESSIONAL JUDGMENT OF

Structured professional judgment (SPJ) is a formal method of evaluating the risk of future violence. Such evaluations are required in numerous contexts, such as parole decisions, release from forensic hospitals, civil commitment, when violence threatens the workplace, among others. Originating in the mid-1990s, the SPJ approach consists of a family of risk assessment measures devoted to specific types of violence. This entry reviews the following topics: brief description of the SPJ approach, SPJ instruments, core assumptions of SPJ, use of the SPJ model in practice, and research support for SPJ.

Description of the SPJ Approach

The SPJ approach is a comprehensive approach to violence risk assessment. It structures the decision-making process from the gathering of information necessary to complete a risk assessment, to rating risk factors, formulating risk, specifying future scenarios of violence, suggesting risk management strategies, and facilitating risk estimates of the likelihood of future violence. It is a method of decision-making that is founded upon empirically supported violence risk factors and well-supported criminological and psychological theories devoted to understanding why people decide to act violently (collectively called *decision theory*, specific examples of which include situational action theory and rational choice theory). It helps evaluators determine the presence of risk factors, which risk factors are most relevant or important in a given case, why a person has chosen to act violently (what motivates, disinhibits, or destabilizes the person's decision-making), what the person might do in the future, what risk reduction strategies make most sense in a given case, and the level of risk a person poses.

The SPJ approach, though structured and comprehensive, does not use equations, formulas, or algorithms to produce numeric estimates of future risk of violence. Some approaches propose to do so, but the developers of the SPJ approach have noted shortcomings in these attempts. For instance, they have argued that actuarial estimates are often based on single samples or a small number of samples; that they often omit important risk factors due to sample dependence; and that their numeric estimates vary across samples and settings. The authors have also asserted that actuarial estimates tend to weight risk factors in a manner that assumes equal weights for all people, which could force evaluators to provide higher weight to certain factors that, in their judgment, had little to do with a person's violence compared with factors that were essential to understanding a person's violence. In addition, according to the authors, actuarial estimates are less geared toward risk management and capturing change over time, and they do not facilitate formulation or scenario planning.

SPJ Instruments

There are a number of SPJ instruments, each containing between 20 and 30 violence risk factors.

The most general, and most widely used, instrument is called the *Historical-Clinical-Risk Management-20* (HCR-20), which is applicable to all forms of violence. The HCR-20 contains 20 risk factors dealing with historical factors (personality disorder, mental illness, past violence, substance use problems, and past noncompliance), recent functioning (violent ideation and instability), and future functioning (adequacy of professional plans, personal support, and stress and coping). In a survey of over 2,000 clinicians, the HCR-20 was found to be the most commonly used violence risk assessment instrument across more than 40 countries. It has been translated into 20 languages and has had several hundred empirical evaluations conducted on it.

There are also SPJ instruments that deal with specific forms of violence, including sexual violence (Risk for Sexual Violence Protocol [RSVP] and Sexual Violence Risk-20 [SVR-20]), stalking (Guidelines for Stalking Assessment and Management [SAM]), intimate partner violence (Spousal Assault Risk Assessment [SARA]), group-based violence (Multi-Level Guidelines [MLG]), honor-based violence (the PATRIARCH), violence screening (the TRIAGE), short-term violence (Short-term Assessment of Risk and Treatability [START]), violence among children (Early Assessment Risk List-20, for Boys [EARL-20B]; Early Assessment Risk List-21, for Girls [EARL-21G]), and violence among adolescents (Structured Assessment of Violence Risk in Youth [SAVRY]).

Core Assumptions of SPJ

The SPJ model makes some basic assumptions. These assumptions are as follows: (a) professionals with appropriate training, education, and experience can make reliable decisions about risk; (b) there are changeable, or dynamic, risk factors that must be included on any risk assessment instrument for the purposes of risk reduction; (c) when dynamic risk factors change, the likelihood of future violence changes in kind; (d) dynamic risk factors must be monitored over time; (e) in general, the more risk factors present in a case, the higher the risk, but that risk is not solely determined by a linear combination of risk factors (i.e., a small number of highly salient risk factors can lead to violence).

Using SPJ in Practice

SPJ instruments share a fundamentally common approach to the violence risk assessment task. There are some slight differences across measures depending on the date of publication. For all measures, evaluators rely on interview information (when possible and not contraindicated) and file-based information (e.g., correctional or psychiatric records; employment records). Supplemental sources of information include collateral interviews (e.g., with family members, victims, or coworkers, when appropriate), observation (e.g., when a patient resides on an inpatient unit), and medical or psychological testing.

In addition to determining which risk factors are present, evaluators are guided through several assessment steps that facilitate answers to the following questions:

- Of the risk factors that are present, which are the most important to understanding why a person has been violent?
- How can the risk factors be integrated to produce a formulation of risk (essentially, why has the person done what he or she has done)?
- What is the evaluator worried the person might do in the future?
- What can be done to prevent the violence?
- What level of risk does the person pose?

These are basic questions that any good risk assessment must address. The SPJ approach simply provides a structure to help evaluators address these questions. It is reflective of a larger principle—supported by theory and research—that human beings make better decisions about complex matters involving many pieces of information within a structure than without structure.

To illustrate the typical SPJ decision-making process, HCR-20 Version 3 will be used as an example. To be clear, all other SPJ instruments use a similar logic. Steps 1 and 2 are simply gathering information and rating risk factors. Risk factors on SPJ instruments are rated based on operational definitions and coding notes. Risk factors are rated as *absent*, *present*, or *possibly/partially present*. No risk factors are deemed, a priori, as definitively more important than others in any given case. That is the work of the evaluator to determine. Nomothetic data (support for a risk factor

at the sample or population level) are treated as support for hypotheses to explore at the case, or idiographic, level. In one case, substance use problems might be more important than child abuse; in a different case, the opposite might be true. Evaluators must have the discretion to determine this.

To facilitate evaluators' judgments of the importance of risk factors within individual cases, SPJ instruments have introduced the concept of idiographic relevance. On the HCR-20 Version 3, this is Step 3. Idiographic relevance of a risk factor is different from its risk-enhancing status in the population. Rather, it refers to the risk-enhancing property at the case level. Just because a person has a risk factor that is supported at the population level does not necessarily mean that it is associated with violence equally strongly, or at all, for any given person. The evaluator's job is to determine how important a given risk factor is for understanding a given person's violence.

This issue of relevance is central to the next step within SPJ, represented in Step 4 on the HCR-20 Version 3, formulation. Formulation is a core competency in most mental health fields. Its essence is to explain why something happened. For example, if a therapist sees a new client who is claiming to be depressed, that therapist needs to know why the person is depressed. What sorts of thoughts lead to her depression? Does she have negative self-evaluations? How does she interpret significant others' opinions of her? Risk formulation is not different. The evaluator needs to know why a person has been violent in order to make decisions about risk and make suggestions for how to prevent future violence.

The SPJ approach allows a variety of conceptually and theoretically meaningful methods of formulation. It generally promotes the integration of risk factors into conceptually meaningful clusters with root causes. Then, it promotes ascertaining how such risk factors influence a person's decision-making about violence. Why does a person think violence can achieve some goal? Why is he not worried about the negative consequences of violence? One of its major recommendations draws from decision theory, an approach with a broad support in criminology and psychology. Essentially, this approach recommends that evaluators consider how risk factors influence a person's decisions to act violently. It describes motivations (i.e., factors

that increase the perceived benefit of violence, such as gaining status, control, or dominance), disinhibitions (i.e., factors that decrease the perceived cost of violence, such as lack of empathy, negative attitudes, or nihilism), and destabilization (i.e., factors that impair careful decision-making, such as impaired cognition, perception, or attention). It should be noted that this approach is also highly consistent with the assumptions of empirically validated risk reduction techniques that focus on offender thinking, such as cognitive skills training or problem-solving skills training.

After formulation, evaluators turn their attention to the future. In essence, this step (Step 5 of the HCR-20 Version 3) asks evaluators to specify what forms of violence they are worried the person might commit in the future, if the person were to be violent, as well as the likelihood of those scenarios. For example, will a person rob a bank, sexually assault a child, beat someone up in a bar, or punch his mother? Scenario planning is used in numerous fields, including military planning, emergency preparedness, health-care planning, and business. It helps people plan in a context of uncertainty, which describes the risk assessment context. In crafting scenarios, evaluators are mindful of the motivations of violence, who might be future victims, and how serious the violence might be. They draw on a person's past acts of violence, but also think about whether any twists or exacerbations of violence might occur.

Next, the evaluator specifies what might be done to reduce the risk of violence. This step (Step 6 on the HCR-20 Version 3) takes into account previous steps (why has a person acted violently and what might she do in the future?) to put plans into place or recommend to others to do so. Evaluators first specify what the warning signs for an escalation of risk would be based on the person's history and future context (e.g., resuming drinking, dropping out of treatment, and getting into arguments with a spouse). Then, they recommend strategies and tactics for monitoring (frequency and method of observation), supervision (its strictness and method), intervention (types of rehabilitation), and victim safety planning (how prospective victims might spot warning signs and cope with stressors).

Finally, based on the preceding, the evaluator can offer summary risk ratings about the likelihood of future violence, how serious it might be, and its

imminence. This is Step 7 on the HCR-20 Version 3. These are narrative, categorical judgments, framed in terms of low, moderate, and high. For reasons discussed earlier, they do not depend on numeric cutoffs or algorithms. This is a principled method for risk communication that is intended to summarize previous steps. A judgment of high risk means that the evaluator has a high level of concern that the person will be violent in the coming 6–12 months, that a high degree or intensity of intervention will be required to mitigate risk, and therefore that the person is at a high priority for the receipt of services and resources.

This method has been criticized by some commentators because it does not involve algorithms or numeric cutoffs, and it does not produce numeric probability estimates of future violence (although these are routinely published in academic articles). Despite the criticism, this method has also been shown across roughly four dozen studies to be as or more accurate than algorithmic approaches to risk estimation. Indeed, as reviewed in the next section, the judgments of low, moderate, or high risk tend to add incremental validity to optimized, numeric (i.e., actuarial) combinations of risk factors.

The Nature of Research Support for the SPJ Model

There have been several hundred empirical evaluations of the SPJ approach as of 2017. The research has occurred across more than two dozen countries. Meta-analyses show that this approach is at least as accurate as the actuarial approach in terms of the predictive validity of risk factors, if not more so. Moreover, changes in risk factors over time have been shown to predict changes in violence in the future. That is, there is support for the dynamic risk of SPJ measures.

Nonalgorithmic judgments of low, moderate, or high risk have routinely been found to add incremental predictive validity to the summing of the risk factors or to other risk assessment measures, including actuarial ones. There are several possible reasons why this might be the case. First, actuarial measures treat all persons the same and presume that all risk factors should have the same weighting across people, whereas SPJ measures do not. They require the evaluator to specify which risk factors are the most important in any given

case. Second, most actuarial measures presume that a simple linear combination of risk factors is the optimal method of determining risk. The SPJ agrees that, in general, the more the risk factors are, the greater the risk. However, it specifically allows for deviations from a linear model. For instance, if a given person were to have an acute psychotic break, be heavily intoxicated, and be experiencing violent ideation, it could be reasonable to conclude that he or she is at high risk of violence. Most actuarial methods would classify such a person as at low risk because there are only three risk factors present. Third, as referred to earlier, putatively precise numeric estimates produced by actuarial methods have yet to be shown to be consistently robust across samples. That is, they change across samples, likely due to the inherent uncertainty and complexity involved in risk assessment. It is difficult to anticipate future factors that affect risk—SPJ methods such as the HCR-20 Version 3 attempt to do so through the inclusion of forward-looking decision aids (e.g., the Risk Management Scale, scenario planning).

CRIMINAL RISK ASSESSMENT, VIOLENCE

Violence risk assessment is a professional task that is required in numerous legal and clinical settings. It has as its most basic premise the identification of persons who pose higher versus lower levels of risk of future violent behavior. More comprehensive approaches also facilitate decisions about why persons have acted violently, why they might do so in the future, and what risk management efforts can be put into place to reduce risk. Such decisions are made daily, thousands of times, across myriad contexts, pan-globally. Common settings include parole decisions, sentencing determinations, discharge from forensic hospitalization, civil commitment, workplace health and safety determinations, immigration hearings, law enforcement case management, community risk management of patients and offenders, bail decisions, and sexually violent predator and other indeterminate sentencing proceedings. Many different professional groups are involved in violence risk assessment: clinical psychologists, psychiatrists, psychiatric nurses, social workers, occupational health and safety workers, law enforcement officers, judges, and immigration officials. In this entry, the following topics are reviewed: a descriptive overview of the task of violence risk assessment; the landscape of the most common applications of violence risk assessment; the evolution of the violence risk assessment

field, including landmark legal events that spurred its growth; major approaches to the task of violence risk assessment; the essential applied tasks involved in carrying out violence risk assessments; the fundamental state of the field in terms of its empirical evaluation; and core gaps to consider moving forward.

Descriptive Overview of Violence Risk Assessment

The essence of violence risk assessment is to make decisions about another person's future behavior. To predict the future behavior of a single individual—the task required within risk assessment contexts—is a complex endeavor. There are numerous pitfalls that can detract from its accuracy and reliability. Most prominent among these is simply the fact that the future is unknown, and there are many unknown future events and circumstances that can elevate or decrease a person's risk for violence. Nonetheless, predictive decisions must be made for legal and ethical reasons.

Credible approaches to violence risk assessment require evaluators (e.g., clinical psychologists, social workers, law enforcement officers) to consider a set of factors that are known through research to increase the risk of violence, on average, across people. These factors are called *risk factors*. Typically, they are assembled together in a manual or a test, with instructions to evaluators on how to rate or code them. Such manuals or tests are called *violence risk assessment instruments or measures*. The tests or measures also have instructions and explanations for evaluators to produce estimates of the likelihood of future violence. Some such measures produce numeric probability estimates, whereas others produce principled, narrative categorical estimates. Regardless of this, evaluators use these measures to guide their judgments about the nature and level of risk posed by a given individual. Researchers evaluate these in terms of their reliability (i.e., Do different evaluators reach the same, or nearly the same, decisions based upon them?) and validity (i.e., To what extent do the measures help to differentiate those who go on to be violent from those who do not?).

The results of a violence risk assessment are then used directly by the evaluator or reported to a

different decision maker (e.g., a judge, a parole board member, a review board member in a forensic setting), to inform any one of a number of vitally important dispositions for which the issue of risk posed by future violent behavior, or threat to public safety, is critical. For example, risk assessment decisions are considered in determining whether a person is sentenced to prison or probation, is granted parole or must remain in prison, is allowed out of the forensic hospital (and whether this must be with an escort or not), and is classified as maximum, medium, or minimum security within correctional facilities; whether a child should be taken away from his or her family in a child protection case; whether an individual with mental disorder can be civilly committed against his or her will; whether a person can be fired from a job; whether a young offender should be tried as an adult; whether a person who has committed a capital offense should be sentenced to death; or whether a person applying for immigration status within a country poses a risk to the public.

Common Applications of Violence Risk Assessment

As noted earlier, there are many settings in which violence risk assessment is required. Here, just a few major ones are described. In mental health law, a person can be involuntarily hospitalized (and hence deprived of liberty) if that person is mentally ill and poses a risk of violence to others (or self). This has been one of the most contentious legal arenas in the risk assessment field. Criticism of the mental health field as state agent spurred the evaluation of the accuracy with which mental health professionals can estimate future risk of violence. Despite legal attacks, most states, provinces, and countries permit involuntary hospitalization of a person due to mental illness in combination with the risk of violence to others (or self). The strictness of requirements varies greatly across jurisdictions. In some, risk of violence must be imminent, and the violence under consideration must be serious and must be against an identifiable person. In others, the risk must not be so clear. Under U.S. law, civil commitment law has been broadened to allow postsentence detention of sex offenders who pose a risk to the public of continued sexual violence (the so-called sexually

violent predator laws). However in traditional civil commitment, the length of stay in hospital is short (often days or weeks); in the sexually violent predator context, most detainees are hospitalized for many years.

Another common application of violence risk assessment is discharge from prison or from forensic hospitalization. In most cases, a person will have been imprisoned or hospitalized for years and becomes eligible for potential release into the community. Partial releases are also possible (e.g., day parole, supervised day leave, unsupervised day leave). In such contexts, parole board members (in the prison context) or review board members (in the forensic release context) must follow guiding legislation to determine whether the release would pose an undue risk to society. For this, they often receive risk assessment reports from psychologists, psychiatrists, or related professionals. They then integrate these reports into their own risk assessments to determine whether release poses an undue risk as defined by statute.

In such contexts, if a person is released, he or she typically will be supervised in the community by a parole officer or by a forensic mental health team. These professionals then engage in an ongoing risk assessment and management role. That is, they adjust and revise the risk assessment over time to ensure that the person under supervision does not pose an undue risk. They have the authority to send a person back to the prison or to the forensic hospital if conditions of supervision are violated or if they deem that the person poses an undue risk to the public. Risk assessment approaches that are used in these contexts must facilitate the tracking of change in risk over time, which is called *dynamic risk*. Some risk assessment approaches do not permit this and hence are of limited utility in these settings.

Another common application is presentence reports to court. Judges often need to know whether a person is safe to serve his or her sentence in the community (e.g., probation) or must be incarcerated to protect the public. Judges have limits placed on them (e.g., first-degree murderers will not receive community sentences, regardless of future risk). However, in some cases, they have discretion about whether a person should receive a custodial or community sentence. In such cases, violence risk assessments play an important role.

Finally, workplaces have a legal duty to protect the safety of their workers. Such threats to safety might stem from asbestos exposure, electrocution risk, or heavy machinery—or they might come from coworkers. This setting has been subjected to much less empirical scrutiny, likely because companies generally are not interested in publicizing the extent of violence perpetrated by their workers. Yet, all companies are subject to occupational health and safety law.

Evolution of the Violence Risk Assessment Field and Major Approaches to Violence Risk Assessment

Johnnie Baxstrom changed the world—that is, the risk assessment world. He also changed the lives of nearly 1,000 people in the same situation he was in. He was serving a sentence for violent crimes including robbery, and he also had a mental disorder. Once his sentence expired, New York state classified him as a dangerous mentally disordered accused, an option available to it in the 1950s and 1960s. This meant that he would be indeterminately imprisoned due to his dangerousness, despite having served his sentence. In essence, he had been predicted to be violent in the future and, despite having served his sentence, was therefore detained. Ultimately, the U.S. Supreme Court deemed that such treatment was unfair and ordered that he and close to 1,000 people in the same situation be released outright or transferred to less secure facilities.

In the mid-1960s, the sociologist Henry J. (Hank) Steadman decided to follow up these so-called dangerous mentally ill offenders to see how many of the 967 went on to commit crimes of violence against others. All 967 had been deemed to be dangerous, that is, likely to commit a serious act of violence in the future if they were released into the community. Steadman and his colleagues found, and published in a series of articles and books, that only a small minority went on to be violent. Indeed, the vast majority of these *predictions of violence* were simply wrong.

This observation shook the academic and mental health fields. Some argued that mental health professionals were incapable of predicting violence. People had been detained arbitrarily, and rights had been violated. At times, psychiatrists

and other mental health professionals had been presumed to be able to accurately predict future violence. Yet, the Baxstrom case changed everything for the concept of *dangerousness*, as it was commonly referred to, and led to the modern era of violence risk assessment.

Sharp criticism of the mental health field followed. Legal commentators derided mental health professionals' abilities in such cases. Along with critical scholarly comment and debate, numerous lawsuits called into question the ability of mental health professionals to forecast future violence with any degree of accuracy. Yet, courts generally dismissed arguments that such a feat was beyond the ken of psychiatry or other mental health fields. By the early to mid-1980s, mental health professionals or their employers were being successfully sued for not taking appropriate action to prevent foreseeable violence against third parties (see the jurisprudentially watershed case, *Tarasoff v. the Regents of the University of California*).

The works of Steadman and a handful of other scholars led John Monahan to declare in his 1981 book *Predicting Violent Behavior: An Assessment of Clinical Techniques* that only “one in three predictions were accurate.” Yet, shortly after this assertion, Monahan himself in 1984 tried to stem the flow of caustic aspersion hurled upon the mental health field. He reminded the field that although only one in three predictions of future violence was accurate, nine in 10 predictions of nonviolence were accurate. That is, although positive predictions were of questionable accuracy, negative predictions fared much better. He opined that perhaps accurate shorter term predictions were possible. He argued that a focus on validated risk factors for violence might bear fruit.

What followed was an acute increase in scholarly interest and activity about how to improve violence risk assessment. Researchers focused on which risk factors were related to violence. For instance, by the mid- to late 1980s, there were dozens of studies on the role that mental illness and psychopathy might play in understanding violence. Shortly after this risk factor stage, scholars developed and evaluated the efficacy of combining risk factors into the so-called violence risk assessment instruments.

In 1993, a 12-item violence risk assessment instrument called the *Violence Risk Appraisal*

Guide (VRAG) demonstrated strong predictive effects in a sample of forensic patients. Estimates of future violence came in the form of numeric probability estimates (e.g., that the patient X has a 72% chance of being violent in the coming 7 or 10 years). This finding spurred the modern *clinical versus actuarial* debate in the violence risk assessment field that had been taken up by Paul Meehl decades earlier. The argument was that formulas (and, generally, actuarial procedures) were better able to make decisions than were human decision makers. Human decision makers, it was argued, were too susceptible to biases and heuristics to make reliable decisions about future violence (or any future behavior, for that matter).

Yet, some scholars questioned whether the VRAG was the long sought-after panacea for the ills that plagued the risk assessment field. For instance, it was developed based on a certain method (i.e., file review without interviews of patients), within a certain setting (i.e., forensic patients), using a single sample, a certain follow-up period, and a particular definition of violence that excluded, for instance, robbery. It was noted that certain potentially important risk factors were not included in the VRAG—previous violence and drug use problems, for instance. Were clinicians really going to ignore past violence and drug use when conducting a violence risk assessment? Numerous other studies suggested that these risk factors were related to violence and hence should be considered in a violence risk assessment. What if the issue was violence in the coming days to weeks rather than 7 or 10 years? And, given that the VRAG was based just on Canadian men, what about women and people outside of Canada?

Shortly after the VRAG was published, another approach to violence risk assessment emerged: the Structured Professional Judgment (SPJ) model. The most commonly used exemplar of this model is called the *Historical, Clinical, Risk Management-20*, the first version of which was published in 1995. According to a large survey of over 2,000 clinicians published in 2014 by Jay Singh, the VRAG is the most commonly used actuarial violence risk assessment instrument across more than 40 countries, whereas the *Historical, Clinical, Risk Management-20* is the most commonly used violence risk assessment instrument of any type across these 40+ countries.

SPJ instruments such as the *Historical, Clinical, Risk Management-20*, like actuarial instruments, include a set of risk factors and a method of determining level of risk. However, they do not limit risk factors to those found to be important in just one study, but rather draw on the larger scientific violence literature. They also do not use equations or algorithms because such equations have yet (as of 2017) to be shown to produce generalizable findings across different samples. SPJ instruments also tend to focus more than actuarial approaches on issues such as risk management and monitoring risk over time.

Interestingly, one of the major developments was the Level of Service approach to risk assessment. This approach was never quite woven into the debates and controversies cited earlier, perhaps because its genesis was within provincial corrections in Canada and because the initial aim of the Level of Service approach was to determine the level of risk for any sort of correctional violation, not violence per se. The legal precedents and controversies unfolding in the United States were mainly within the mental health context, not within the correctional context. Nonetheless, the Level of Service system represents probably the first empirically based risk assessment process with widespread adoption. However, historically, it has not focused on violence as an outcome but, rather, any type of criminality or breach of conditions.

It should be noted that both actuarial and SPJ approaches, despite their differences, are improvements in what preceded them, which was essentially unstructured approaches that depended almost entirely on the skill and experience of the evaluator. Large discrepancies across evaluators existed. It has been demonstrated that structured approaches such as the actuarial and SPJ approaches are more reliable and valid than unstructured approaches.

Carrying Out Violence Risk Assessments

Fundamentally, when carrying out violence risk assessments, evaluators need to consider and collect information from a variety of sources, including an interview with the person of interest (if not contraindicated as in some law enforcement or workplace contexts); a thorough review of any

official files (e.g., criminal history, treatment history, institutional files, employment records); observation (in the case of professionals working on inpatient units where the person of interest resides); psychological testing, if available; and interviews with collateral sources (e.g., family members, coworkers, victims).

Areas of functioning that should be covered within a risk assessment include, but are not limited to, a person's history of violence and violent ideation, plans for the future, health and mental health history, past criminal involvement, history of incarceration, substance use history, relationships, educational and employment functioning, peer network, use of leisure time, personality and attitudes, and gang involvement. With respect to a history of violence, evaluators are interested in a variety of factors, including its frequency, severity, pattern, trajectory, victims, weapon use, who the victims are, and the ostensible motivations for violence. It is also important for evaluators to ascertain how the person felt before, during, and after any past violent incidents because there are important differences between people who enjoy being violent and those who are anxious while being violent.

Then, the evaluator collates all the information, completes one or more violence risk assessment instruments, and makes recommendations to decision makers about the level of risk and, depending on the referral question, a formulation of violence, scenarios of future violence, and risk management and reduction strategies. As mentioned previously, this is not a simple task, and the responsibility for such decisions ultimately rests with the evaluator and not with the measures he or she used. Tests and measures are just aids that professionals use.

State of the Field of the Empirical Evaluation of Violence Risk Assessment

There are numerous books, chapters, and articles that review the empirical findings on violence risk assessment. Before the 1990s, there were few published studies on the reliability and validity of violence risk assessment. As of 2017, there are hundreds of such studies. Despite some variability in findings, most research indicates that risk assessments can be conducted with a reasonable degree of reliability (i.e., agreement between

raters) and produce moderate to large effect sizes with future violence. That is, they are much better than chance, but far from perfect. There is also some research demonstrating that the nonnumerical summary risk ratings produced by SPJ instruments are as or more accurate than actuarial methods. Moreover, studies also indicate that instruments designed to capture change in risk factors over time are able to do so and that such changes are associated with concomitant changes in future violence.

Core Gaps to Consider Moving Forward

As with any field, despite considerable progress, there is always more to do. For instance, there remain some contexts, such as workplace violence, where the reliability and validity of traditional measures have been subjected to much less evaluation. Research tends to suggest that risk assessment instruments perform comparably for men and women, although there is much less research with women and girls relative to men and boys. Research has also shown that most contemporary risk assessment instruments perform comparably well across different countries. However, within countries, more research is needed among ethnic minority groups. Finally, the field is in need of implementation research. Despite hundreds of studies showing reasonable reliability and validity, there are many fewer evaluations of the success of agencies to implement risk assessment approaches. Although many agencies do so well, as of 2017, the evidence remains rather anecdotal.

CRIMINAL STIGMA

Stigma has been studied in multiple disciplines (e.g., psychology, sociology, anthropology, and criminology) and conceptualized in various ways. In general, stigma is defined as a measure of shame or disgrace brought on by physical and/or mental qualities differentiating individuals from

the broader population. Sociology further refines this definition by adding a discounting feature—*normal* individuals use stigma to discredit accomplishments and stereotype those deemed different. Stigma may be visually obvious (overt), such as race and individuals with physical disabilities, or a concealable identity (covert), such as criminal status. However, this *criminal* or *offender* identity is no longer concealable when individuals are required to disclose their status for community engagement. *Criminal stigma* intersects psychology and criminology to explain how the label *offender* or *criminal* negatively impacts an individual's life upon release. Ex-offenders in many states are unable to vote and face financial and residential restrictions. Most notably, criminal stigma decreases the ability of ex-offenders to find legal employment. This entry focuses on the development of stigma, its impact on ex-offenders, and how it interacts with racial stigma to limit successful reintegration into society.

Development of Stigma

Erving Goffman outlined three types of stigma people may encounter: (1) physical deformities (e.g., cerebral palsy, hearing impairment), (2) mental deformities (e.g., depression, schizophrenia), and (3) tribal stigma (e.g., religion, race). For stigma to have a negative impact, individuals not only need to be aware they are stigmatized but also need to anticipate how others will perceive them because of it. Bruce Link and Jo Phelan further developed Goffman's concept by framing stigma as a convergence of five components: labeling, stereotyping, discrimination, loss of status, and disconnection from the broader population. An important feature of stigma is the negative reaction of others.

Criminal stigma has received the most attention in labeling theory. This theory describes the process through which offenders internalize negative labels and attitudes. Societal reaction to initial criminal deviance (primary deviance) transforms the way in which an offender views himself or herself and thus leads to additional and repeated deviance (secondary deviance). Secondary deviance, or rather the adoption of a deviant identity, only develops if the offender is caught. Once this occurs, the acceptance of the criminal label as truth will activate criminal stigma.

Individuals labeled as offenders are more likely to recidivate than those who avoided the official *offender* label. One possible reason for this relationship is that people labeled as offenders will anticipate discrimination in the future due to their criminal status and therefore see no reason to adhere to conventional standards. According to modified labeling theory, labeling and societal stereotypes may lead to identity changes and negative views of self. These individuals tend to believe that they will be seen as criminal regardless of prosocial community engagement.

Negative Mental Consequences of Stigma

Stigma has been linked to negative self-esteem and self-efficacy. When individuals are low in these qualities, it hinders their ability to cope positively in future situations and can lead to detrimental outcomes such as depression and anxiety. It has also been linked to increased risk-taking behaviors. With regard to ex-offenders, perception of stigma has been correlated with withdrawal from society and increased probation violations and other maladaptive behaviors. Although not all stigmas lead to maladaptive coping strategies, it may still negatively affect those closest to the stigmatized individual. For example, having a criminal parent may stigmatize a child as someone whose genetic pool is morally bankrupt and should be avoided.

Criminal Stigma and Limits to Reintegration

Ex-offenders are stigmatized by the label *ex-offender* which makes it difficult for them to engage prosocially in society. Positive interactions between ex-offenders and nonoffenders in the community help reduce stereotypes associated with prior incarceration. Community engagement includes many qualities such as owning a home, residential stability, having a license, and employment. This section focuses on three domains: employment, civic engagement, and residential restrictions.

Employment

Legal employment is an important step to reducing recidivism and successfully reintegrating

into society. However, out of all stigmatized groups, ex-offenders are least likely to get hired. Employers tend to be risk-averse and indicate that they view ex-offenders as more unreliable, prone to drug- and alcohol-related issues, and expect negative reactions of other employees. These reactions, in addition to the gap in employment history while incarcerated and a lack of prior experience, make it nearly impossible for offenders to secure legal employment. Even when legal employment is secured, they make 10–30% less than comparably placed nonoffenders. The ex-convict label outweighs any good characteristics an individual may possess.

Civic Engagement

Political involvement is an effective mechanism for reducing the stigma of incarceration. Denial of civic participation, which includes the right to vote, run for office, and serve on juries, reminds offenders that they are not valued members of the community. This further highlights their outcast status and hinders reintegration. Ex-offenders are denied these benefits because they are viewed as morally incompetent. People fear that allowing ex-offenders to vote would change the political process. Of the 50 U.S. states, 48 have some form of sanction on voting rights for ex-offenders. In general, ex-offenders acknowledge the importance of civic participation with desistance. However, if they feel they will be rejected regardless of their prosocial engagement in the community, they lose incentives to obtain a *law-abiding* status.

Residential Restrictions

Residential restrictions were created with the idea of minimizing the risk of releasing offenders. Law-abiding citizens fear the encroachment of ex-offenders in their community as they believe ex-offenders will bring crime and decrease property values. This limits the ability of many ex-offenders to leave highly disadvantaged areas likely contributing to their involvement in crime in the first place.

Dual Stigma: Crime and Race

Race is also an attribute that is highly stigmatized, and it exponentially increases the negative impact

of criminal stigma. Therefore, having both a racial and a criminal stigma is highly detrimental. For example, being both African American and an ex-offender makes it nearly impossible for individuals to secure legal employment. Stigma is similar to stereotyping as it produces an expectation of how someone will behave. These stereotypes may lead employers to perceive African Americans and Hispanics as more dangerous, deviant, lazy, and criminal than European Americans.

Devah Pager found that having a criminal record is one of the worst qualities a person can have on a job application. However, minority status appears to be just as, if not more, detrimental. Pager conducted a study of race and crime on employment. Job applications with identical qualifications were sent to several employers with changes only made regarding race and criminal status. Four groups were assessed: noncriminal African American, criminal African American, noncriminal Caucasian, and criminal Caucasian. Across all groups, having a criminal record reduced the likelihood of receiving a callback. However, race showed a more significant impact. African Americans without criminal records were less likely to receive callbacks than Caucasians with a criminal record.

As Pager noted, individuals may soften the impact of criminal stigma with personal contact. An in-person or over-the-phone interview allows the ex-offender to explain his or her charge. However, this process also showed racial bias. For Caucasians, the effect of criminal stigma diminished when they were given an opportunity to defend themselves. However, for African Americans, personal contact exacerbated the effects of the criminal record because it likely confirmed the employers' previously held beliefs that they are more prone to criminality.

The issue of race also permeates other aspects of criminal stigma. African Americans are disproportionately involved in the criminal justice system. This results in a high percentage being disenfranchised or disqualified from services such as welfare, financial aid, and public housing. Minorities are also more likely to be in communities characterized as high in disadvantage, poverty, and crime. It becomes a cycle of stigma. Minorities, already stigmatized by their race, are stereotyped as more prone to crime. As a result, they are policed more and generate more arrests. This

leaves them with an additional criminal stigma that further limits their ability for success in the community.

Reducing the Effects of Stigma

It is evident that current policy is ineffective in reducing the number of people reoffending, with roughly two-thirds of ex-offenders returning to prison. Not only is it detrimental to public safety, prison is becoming increasingly costly. It is no longer affordable to incapacitate offenders. Addressing the barriers to reentry and reducing stigma are becoming imperative as more and more offenders are released into the community.

Stigma has detrimental effects on the way people expect to be treated and thus how they feel about themselves. Research has shown that stigmatized individuals may be more prone to mental health deficits and maladaptive behaviors. However, there are ways to reduce stigma. Men who have strong family ties while in prison are more likely to succeed once released. They are also more likely to succeed if they are married or take on parenting roles.

Employment is one of the most effective ways to reduce recidivism. It is not only beneficial for reducing crime by reducing opportunities but helps change the offenders' negative identity and gives meaning to their lives. Therefore, it would be beneficial to both the ex-offender and the community to consider policies that reduce criminal stigma. Some current government programs provide employers tax breaks and other financial incentives to hire ex-offenders. In addition to these programs, many civil rights organizations are pushing for a *ban the box* policy that would give offenders a fairer chance in the employment process. This policy calls for the removal of prior conviction information on the job application, allowing offenders to be judged on their qualifications before having to divulge their prior criminal record.

Desistence research finds that social ties to family are beneficial to reentry success. For example, good-quality social ties to family may lead to ex-offenders acquiring a job through personal connections. Families are more likely to forgive an offender's criminal history. This helps reduce stigma and build social bonds. Familial ties are also beneficial because they produce a controlling effect on

the offender, provide emotional support, and help facilitate changes in antisocial attitudes or identity.

Research shows that the most critical period for failure is within the first 6 months of release. After 7–10 years without criminal incidents, very few people reoffend. Therefore, sealing records of low-risk offenders after 7 years without a reoffense might also be a minimally controversial option. In Canada, most offenders have the opportunity to seal their records by applying for a pardon (although some are excluded, e.g., sex offenders). To request a pardon, misdemeanor applicants must demonstrate good behavior in the community for 3 years. Felony applicants are required to wait 5 years. Committing a crime within that period makes the offender ineligible. This pardoning process provides offenders with incentives for good behavior. The United States could benefit from an incentive program as it could lift the residential, financial, and voting restrictions that leave an individual disenfranchised and disengaged from the community.

Implications

Stigma reduces the quality of life for all those affected. It generates feelings of shame and self-consciousness that leave people feeling isolated. Stigmatized individuals are often dehumanized, devalued, and viewed as outcasts. The stigma of criminals is perpetuated by the idea that offenders choose to commit crime and therefore are undeserving of resources. However, noting the detrimental effects of stigma and its negative impact on crime, it could be beneficial for all individuals and the broader society to address these issues.

CRIMINALIZATION HYPOTHESIS

The term *criminalization* typically refers to a process in which behaviors once not defined as illegal become so through a legislative process. The world of substance use and abuse includes numerous such examples. In the United States, the use and possession of LSD, for example, was not illegal until the mid-1960s. Alcohol production and consumption in the United States was criminalized at one point and then *de-criminalized* when the legislation supporting it was repealed. What has come to be called the *criminalization of mental illness*, or the *criminalization hypothesis*, has a

somewhat different narrative. While having a psychiatric illness itself is not *criminal*, some of the behaviors that may stem from an individual's illness are defined as illegal, opening up the individual to arrest. This entry provides background and highlights the effects of criminalizing mental illness, which has resulted in large numbers of individuals with mental illness being held in prisons and jails rather than in mental health facilities. Federal approaches in the United States that began in the 1990s, such as the enactment of the Mentally Ill Offender and Crime Reduction Act as well as funding strategies of the Bureau of Justice Administration and the Substance Abuse and Mental Health Services Agency, have encouraged collaboration between local criminal justice systems and mental health agencies to help offset this problem.

The term *criminalization* was first applied to mental illness in a 1972 article by California psychiatrist Marc Abramson. He observed that, following passage of highly restrictive laws governing the use of civil commitment by the California legislature, increasing numbers of persons with mental illness were being arrested, often charged with low-level misdemeanors, because they were seen as not meeting the new, stricter criterion of involuntary commitment to a psychiatric facility. The Lanterman–Petris–Short Act of 1969 was the first law of its kind in the United States to impose strict new guidelines for involuntary confinement of persons with mental illness. Replacing the rather liberal and often quite vague language of previous laws, the Lanterman–Petris–Short statute imposed strict guidelines that required an individual to be deemed a danger to himself or herself, or others, or be grave disabled—that is, unable to meet basic necessities of life (i.e., food, clothing, and shelter) due to mental illness. In the years following its passage, the Lanterman–Petris–Short statute became a model for reformed civil commitment laws across the 50 states. These new restrictions greatly reduced the number of persons who were committed to state hospitals, sometimes leaving them at risk of engaging in deviant behaviors that would come to the attention of police.

Civil commitment reform was but one factor that drove this process. The deinstitutionalization process, which resulted in the discharge from and

denial of admission to state hospitals of hundreds of thousands of individuals, left many individuals without the treatment and support they needed and community-based mental health services that were intended to replace hospital-based services failed to provide.

Prior to the passage of these new laws, persons with known mental illnesses whose behavior was annoying, disorderly, or threatening could be transported to a psychiatric hospital and confined there until they were deemed to have improved. In the post-reform era, however, police officers who were summoned to manage such individuals discovered that many failed to meet the new criteria for involuntary admission. Faced with the need to manage such situations, officers increasingly used arrest, often on low-level charges such as shoplifting, disorderly conduct, trespassing, and other misdemeanors, as a means of managing the problems posed by persons with mental illness. In the following decades, it became clear that behavior that was, in reality, the result of serious mental illness was causing an increasing number of persons to be confined in the nation's prisons and jails, with the result that, by the 1990s, large urban jails, such as the Los Angeles County jail system, Rikers Island in New York City, and Chicago's Cook County Jail, each housed more individuals with mental illness than any psychiatric hospital in the nation.

That such would be the case was predictable based on what has come to be called the *hydraulic* or *balloon* model of social control, which argues that the social control of deviance may be shared by a variety of specialized systems, such as the mental health and criminal justice system, but that if one system reduces the number of persons it detains, another system's population will increase. Thus, if the mental health system incapacitates fewer individuals, as it has in the postdeinstitutionalization and commitment reform era, the criminal justice system's population is likely to increase.

While there is a substantial body of research demonstrating the excessive number of persons with mental illness in the criminal justice system, the notion that most of the individuals with mental illness are detained or convicted on low-level misdemeanors has not been borne out by data. In fact, data on arrest among public mental health systems' clientele indicate that many are arrested

on serious charges, including felony property crimes, crimes against persons, and drug crimes. These data are not consistent with the criminalization paradigm as originally advanced. Studies of police management of episodes involving persons affected by mental illnesses likewise fail to show that a significant criminalization process is at work. Alternative formulations have been developed emphasizing criminogenic risk factors such as poor housing and unemployment, exposure to social networks populated by persons who engage in substance abuse, and other factors known to promote criminality in the general population. It has been argued that reduction in the incapacitating effects of institutionalization, rather than the overuse of the criminal justice system, can explain some of what appears to be excessive justice system involvement in this population.

Despite numerous critiques of the criminalization hypothesis, most actors involved with this population, including the police, mental health officials and advocates, and judges and other officials from the correctional system, agree that the current prevalence of mental illness in the justice system is too high and that steps need to be taken to reduce that involvement. At the federal level, the Mentally Ill Offender and Crime Reduction Act and the Bureau of Justice Administration have provided support for programs that encourage collaboration between local criminal justice and mental health agencies to divert the offenders described by the criminalization model (i.e., low-level, nonviolent misdemeanants) from the justice system to mental health services. These have taken the form of police-based diversion programs, mental health courts, and other services. These programs, which began in the 1990s, have shown reductions in the number of arrests and jail days experienced by persons with mental illness in the jurisdictions where they have been enacted.

CRIMINALNESS

Criminalness has been defined as a nonprosocial behavior that breaks from social conventions and violates the rights and well-being of others. It includes unlawful behavior; however, criminalness may or may not lead to arrestable offenses. Examples of criminalness include abuse of sick leave, taking office supplies for out-of-office use, drug possession, property crime, and/or person and violent crimes.

Criminal behaviors are usually produced from complex interactions among personalities, relationship with others, living environments, and other crime-related factors. Likewise, recidivism, or reoffending, can be influenced by many of these factors. Criminalness is a concept encompassing the factors that lead individuals to offending or reoffending. Without relying on a specific criminological theory, it can be an effective construct in rehabilitation, referring to individuals' crime-related problem separately from ethics, morals, or a strong negative connotation such as *bad* or *wrong*. Thus, the conceptual advantages lie in its comprehensiveness and its independence of specific theories, ethical judgments, and particular theories.

This entry defines and describes concepts related to criminalness with a particular focus on individuals involved in the justice system. Exploring criminalness including its quantitative and qualitative aspects, internal and external expressions, and its relationship to personality and psychopathy, effective treatment plans can be designed and a reduction of criminalness is possible.

Concepts

Conceptually, criminalness is not explicitly an explanatory concept. The argument that one became criminal because of his or her high criminalness is no longer a tautology. The range which the concept covers is broad, and it can vary depending on the context and those who use the term. A conceptualization of criminalness has been put forward by Robert Morgan and colleagues. Their conceptualization refers to violating the rights and well-being of others and may lead to arrestable offenses. In terms of retribution and restitution, seriousness of offense and damages to victims and society are emphasized. From a rehabilitation and crime-prevention viewpoint, the risk of recidivism stands out as an essential issue. Having a broad context, it can also include some misconducts of inmates that are not criminal in nature, such as refusing to take medicine when they know the medical treatment may contribute to better functioning.

Quantitative and Qualitative Aspects of Criminalness

Broadly speaking, criminalness can vary in quantity and quality. The quantity of criminalness involves comparing criminals in a rank order and identifying the severity of a particular case. It can be indicated by criminal history, damage caused by their criminal behaviors, beliefs or attitudes that support or neutralize criminal behavior, relationship with antisocial associates, intention or motivation to desist from their antisocial lifestyles, and risk levels derived from risk assessment tools. From the viewpoint of treatment, it is similar to how much criminogenic needs (i.e., dynamic variables that contribute to crime) a criminal has and how much resources are assigned to deal with them.

The quality of criminalness refers to the factors involving criminal behaviors but does not contribute to ranking criminals along a *seriousness* spectrum. Rather, these factors can help with planning appropriate treatment interventions. It is sometimes difficult to divide quantitative and qualitative aspects of criminalness. Crime type, for instance, does not necessarily tell the seriousness of the offender (i.e., It is difficult to compare a sex offender with a drug offender.). Diversified patterns of crime type, however, can be interpreted as an indicator of serious criminalness. Another factor of criminalness is gender, though again whether the offender is male or female cannot be paired with the seriousness of crime. Additionally, density rates of criminal behavior, whether the offender committed a number of crimes during a short time period or has committed crimes intermittently for a longer period, are also difficult to convert to seriousness of criminalness. Another factor, motivation—what those exhibiting criminal behavior want, what they expect, and what they actually get from their criminal activities—helps define criminalness and is generally informative when planning treatment intervention. Motivation to desist from crimes is also important and the reasons for it are diverse, whereas they may not directly lead to decision-making about how intensive interventions should be assigned.

Internal Expression of Criminalness

Cognitive Components

Criminal thinking, characterized by particular attitudes, beliefs, and rationalizations offenders use to justify their criminal behavior, is regarded as an internal expression of criminalness. Offenders more likely stop consideration or try to find shortcuts in order to avoid problems, distract themselves by getting involved in other activities, tend to misidentify their own wants as needs, underestimate the likelihood of being arrested, and justify their criminal actions afterward. Another cognitive characteristic that can be related to criminalness includes traditionalism. Criminals are less favorable toward conservative social environments, paying less attention to moral standards. In the practice of correctional rehabilitation, these tendencies are accompanied

with distrust in correctional organizations, staff, and programs that hinders successful rehabilitation. In addition, most criminals are characterized by egocentricity, or giving priority to their own benefits over others. These factors are not measured by criminal behaviors; therefore, it can be used as an explanatory factor of crime.

Affective Components

Criminalness is also expressed in affective or emotional aspects. Some criminals are characterized by their sensitivity against emotional stimuli. For instance, some of them are so nervous, sensitive, and vulnerable that they easily feel mistreated, discriminated against, disregarded, victimized, or betrayed. These tendencies make them frustrated and stressed, at times responding with criminal behaviors. On the other hand, some types of offenders are impervious to emotional stimuli. Not only do they hardly empathize with others, but they have difficulty in identifying their own feelings, making it difficult for these individuals to explain the motivation or reasons for their underlying criminal behaviors.

External Expression

External expressions overlap strongly with behavioral expressions. Apart from criminal behavior itself, there are other representing features. Two common features are impulsivity and recklessness. Most offenders take actions thoughtlessly without caution or plans. Furthermore, many dislike tediousness activities and prefer excitement without avoiding danger and harm. These tendencies are associated with binge drinking, speeding, drug abuse, or indiscriminate sex lives. Another significant external expression is aggression, which can take various forms such as physical violence, sexual harassment, depriving property, or verbal abuse.

Criminalness is reflected in patterns of interpersonal relationships. As for choice of associates, offenders are inclined to associate with persons who have antisocial attitude, antisocial personality, and criminal records. Those relationships can give opportunities to learn further criminal behaviors, attract them to crime-provoking situations, and reinforce their antisocial attitudes.

In the field of criminal justice, offenders' disobedience or resistance can also be seen as an expression of criminalness. Police officers tend to see disobedient suspects as more serious cases, and correctional officers are more likely to expect cooperative participants to be successful after their release. Although some studies revealed that offenders' misbehaviors are not necessarily predictive of recidivism, if the offending behavior hinders successful completion of treatment programs whose effects are supported by empirical evidence, the offending behavior is an indirect factor contributing to criminalness.

Comparing to Other Concepts

Principles of Risk-Need-Responsivity

As criminalness is a practice-based concept that is used in terms of offenders' rehabilitation, it overlaps with the principles of the Risk-Need-Responsivity model. The Risk principle aims to match the intensity of service with risk levels so that higher risk offenders receive more intensive treatment. The word *risk* here is used as an equivalence of likelihood of reoffending. The Need principle targets criminogenic needs, instead of focusing on noncriminogenic needs, asserting that identifying offenders' individual needs (e.g., work performance, alcohol use, engagement in leisure, and recreational activities) leads to effective treatments. The Responsivity principle refers to the benefit of adapting the delivery of service according to the setting of service and to relevant characteristics of individual offenders, such as their motivations, preferences, learning styles, and personalities.

Much about one's criminalness can be described in terms of risk, needs, and responsivity. In a way, risk can be understood as a vertical axis or weight of criminalness. More serious criminalness requires more careful assessments and more intensive interventions. Similarly, needs and responsivity do not directly determine the amount of interventions but can help direct contents and delivery of interventions.

Psychopathy

Psychopathic personality (psychopathy) is defined as a set of particular personality traits

such as callousness, grandiosity, and pathological lying that may occur in the context of crime or socially deviant lifestyle. It is usually operationalized by the Psychopathy Checklist–Revised and applied to the correctional practice. It overlaps with the diagnosis of antisocial personality disorder, which is characterized by antagonism (manipulativeness, deceitfulness, callousness, and hostility) and disinhibition (irresponsibility, impulsivity, and risk-taking).

These concepts and criminalness overlap. Criminalness is conceptually aimed to cover a broader range of factors leading to crime, whereas both antisocial personality and psychopathy place an emphasis on personality traits concerning affective and interpersonal functioning. It is neither that all with criminalness have psychopathic personalities nor that all psychopaths have criminalness. However, criminalness developed by those with psychopathic personality tends to be more serious and more difficult to engage in treatment.

Criminalness and Personality

Although criminalness is not a personality trait by definition, some traits can increase the likelihood that one develops criminalness. To name a few, hostility, negative emotion, impulsiveness, and egocentricity have been studied in criminology. More general personality theories also shed light in understanding criminalness. The five-factor model identifies basic components of personality: openness, conscientiousness, extraversion, agreeableness, and neuroticism. Among them, agreeableness, conscientiousness, and neuroticism are known to demonstrate consistent relationships with antisocial and aggressive behaviors. However, it should be noted that these traits do not necessarily cause criminalness. More likely, they interact with environmental factors. For example, those with lower conscientiousness and lower agreeableness tend to have difficulty in developing relationships with prosocial associates, remaining in their secure jobs, and refraining from transient pleasures. These tendencies presumably push them into situations with higher risk of committing crime. In addition, they also make it difficult for treatment providers to implement interventions effectively, contributed by their greater criminalness.

Changing Criminalness

According to official rates of crime, rates for prevalence and incidence of offending appear highest during adolescence with the peak around 17 years of age. The majority of criminal offenders are teenagers, and most of them desist from offending by the late 20s. This tendency is observed among males and females, for most types of crimes, and in many nations. However, some offenders demonstrate life-course-persistent antisocial behavior.

External events can contribute to a reduction in criminalness. Studies on desistance pointed out the importance of situations that provide supervision, new opportunities of social support/growth, the opportunity for identity transformation, and a change in routine activities. To be specific, marriage/spouses, military service, reform school, work, and residential change can redirect individuals toward prosocial lives.

Incarceration in correctional facilities can impact one's criminalness. On the one hand, it provides offenders with opportunities to leave their antisocial associates such as gang groups. In addition, they are encouraged to reflect on their lives, recognize their responsibilities, and develop relationships with family members. Through various treatment programs in institutions, a reduction in criminalness is possible. On the other hand, incarceration can increase criminalness in several ways. Through interactions with other inmates, offenders might learn more sophisticated methods to commit crimes, come to justify their crimes, detach from their prosocial relationships, or become more indifferent to the outside world.

CRIMINOGENIC NEEDS

Offenders have many needs. They may have mental health issues, physical complaints, and substance abuse, to name a few. Treatment providers often attempt to address and alleviate these needs. For high-risk offenders, the needs are many, and the ability to meet these needs often outstrips the supply of available services. Criminogenic needs are those needs that are amenable to change, predict offender criminal behavior, and are possibly causal. This entry begins with a description of criminogenic needs and describes research findings in support of this concept to give service providers a beacon to which to direct their treatment efforts and make more efficient and effective uses of their resources.

Development of the Concept of Criminogenic Needs

The period between 1950 and the mid-1970s was arguably the zenith of the offender rehabilitation movement with rehabilitation widely accepted as a legitimate goal for corrections. Then, in 1974, a review of the treatment literature by Robert Martinson and his colleagues cast doubt on the effectiveness of rehabilitation services to reduce offender recidivism. They reviewed 231 controlled studies of various interventions designed to *treat* offenders. This included studies on system interventions, such as probation and prisons, typically not what most therapists would call *treatment*. When only psychosocial-type treatments that measured recidivism outcomes were examined (83 studies), 48% showed a reduction in recidivism. Because less than half of treatments were effective, critics of rehabilitation concluded that *nothing works*.

Advocates of rehabilitation, however, took up the challenge of investigating why treatment was not more effective. In 1990, D. A. Andrews, James Bonta, and Robert Hoge conducted a narrative review of the offender treatment literature. It was not a systematic and comprehensive review, but one that sampled the literature. They noted that programs targeted a variety of offender needs, and the ones that were most effective had certain treatment goals. Andrews and his colleagues

differentiated between two kinds of offender needs: criminogenic and noncriminogenic. Criminogenic needs were offender needs that, when successfully addressed by treatment, were associated with reductions in recidivism. Noncriminogenic needs that were targeted by programs showed little association with recidivism reduction. From this observation, the need principle of effective offender rehabilitation was formulated: target criminogenic needs in treatment.

Dynamic Nature of Criminogenic Needs

Criminogenic needs are a particular subset of factors that measure the risk of criminal behavior. There are two sets of risk factors: static and dynamic. For example, the number of prior arrests or a history of drug abuse as assessed in a moment is fixed and unchangeable. Static risk factors predict criminal behavior, but they cannot serve as treatment targets. Once someone is arrested or uses an illegal drug, that fact remains. Any possibility of change can only be unidirectional (e.g., the number of prior arrests can increase).

The second set of risk factors is *dynamic* and bidirectional and is labeled as criminogenic needs. Because of the dynamic quality of these risk factors, they can serve as targets for treatment interventions. An example is *current* substance abuse. An offender may present with a cocaine addiction, but it is possible that with the right rehabilitation program the offender can learn to lead a drug-free life and also decrease the probability of future criminal behavior. The bidirectional nature of criminogenic needs also implies that risk can increase. Thus, to extend the example, someone who is drug-free and then becomes addicted to cocaine increases his or her risk of criminal behavior.

In order to demonstrate a criminogenic need's dynamic validity, assessments of the need must be conducted at least two points in time to yield a measure of change. This change measure from assessment to reassessment can then be examined to see whether the changes predict future criminal behavior. For example, if an offender stops abusing drugs, then does the probability of recidivism decrease? Or, does the likelihood of recidivism increase when the person becomes addicted to an illegal drug? A static risk factor requires only one assessment of the variable of interest that is then

examined to see whether it predicts future behavior. Static risk validity requires a simple longitudinal research design, while dynamic risk validity requires a multiwave longitudinal design.

A multiwave study of pro-criminal attitudes provides an illustration of the dynamic validity of this criminogenic need. Probationers were administered a paper-and-pencil measure of criminal attitudes at intake and 6 months later, with recidivism measured 1 year after the reassessment. Those probationers who initially scored in the moderate range in pro-criminal attitudes but then showed a decrease at the second assessment had a 10% recidivism rate. Probationers who showed no change in their attitudes demonstrated a recidivism rate of 38%, while the probationers who showed an increase in their pro-criminal attitude scores had a rate of 57%.

Major Criminogenic Needs

The Psychology of Criminal Conduct perspective of criminal behavior forwarded by Bonta and Andrews includes a description of the major risk/need correlates of criminal behavior called *the Central Eight*. The first risk/need factor, criminal history, is a static risk factor. The other seven risk/need factors are criminogenic needs. The seven criminogenic needs are pro-criminal attitudes, antisocial personality pattern (APP), education/employment, family/marital, leisure/recreation, substance abuse, and companions. All of them are modifiable and can change through deliberate intervention.

APP is the most complex of the criminogenic needs. APP consists of more discrete, dynamic factors such as impulsiveness, adventurousness, pleasure-seeking, negative emotionality, and a callous disregard for others. Each of these characteristics by themselves is insufficient to explain criminal behavior. There are many people who have poor self-control, are risk-takers, or are simply disagreeable persons who do not violate the law. However, combine these characteristics and a criminal lifestyle emerges. From a treatment perspective, addressing APP means having subtargets such as improving self-control or empathy.

There are a number of needs not found in the Central Eight that has traditionally been, and in some circles is still viewed as, important for

offender rehabilitation. One major set of needs are indicators of psychological health. Service providers in correctional and forensic settings up to the turn of the 21st century highly favored treating, for example, poor self-esteem, anxiety, and feelings of alienation and depression. However, evidence from meta-analytic reviews of the prediction and treatment literature has found these needs to show little association with recidivism. That is, they are *non*criminogenic needs. Although a small portion of offenders with mental illness do commit offenses because of their symptoms, for the vast majority of offenders even severe mental health disorders do not predict general or violent recidivism. Important exceptions include problems with impulse control, callous and hostile emotions, and reckless risk-taking. However, this constellation of psychological problems is captured in the Central Eight's APP.

Another set of variables missing in the Central Eight are sociologically based factors. In criminological theorizing, an individual's position in society is often seen as a cause of crime. More specifically, being in a disadvantaged social position is associated with criminal behavior. Those most likely to engage in crime are individuals who are poor, young, or from a minority group. Furthermore, the solution to the crime problem is to correct social injustice and inequality. As research on this explanation of crime accumulates, showing only small associations with criminal behavior, this perspective of criminal conduct has become more difficult to defend.

Evidence on the Importance of the Central Eight's Criminogenic Needs

Evidence in support of the Central Eight's criminogenic needs comes from two important sources: the effectiveness of treatment literature and the development and application of offender risk/need assessment instruments. Offender rehabilitation programs attempt to address the needs of offenders, and these programs have, as already noted, targeted a variety of offender needs. The simple question is whether alleviating certain offender needs (criminogenic) is more likely to result in reduced offender recidivism than other offender needs (*non*criminogenic). Reviews of the offender treatment literature clearly show that there is an

important distinction related to needs that is to be made.

Table 1 summarizes the importance of targeting the criminogenic needs described by the Central Eight risk/need factors. The table is based on a number of meta-analytic reviews of the literature. Also shown in the table are the mean effect sizes when noncriminogenic needs are the focus of treatment. Treatment programs that target criminogenic needs show modest to moderate reductions in recidivism. For example, a mean effect size of $r = .11$ for leisure/recreation translates into a recidivism rate of 55.5% for the control group and 44.5% for the treated group. At the high end of effect sizes, an r of .29 for addressing family/marital issues in treatment corresponds to a rate of 64.5% for the control group and 35.5% for the treatment group. Programs with the goal of addressing noncriminogenic needs show small effects and even negative effects (i.e., recidivism increases with programs intended to instill fear such as Scared Straight).

Offender assessment has two important functions. First, it should reliably predict and differentiate offenders in their likelihood to reoffend. That is, the assessment should be able to

classify offenders into a category of risk (e.g., low, medium, high) or along a scale where offenders can be situated relative to each other in terms of risk. The second important function, and this use only emerged in the late 1970s, is to guide interventions that are intended to reduce recidivism. Predicting recidivism can easily be accomplished by using assessment instruments that consist of mainly criminal history, static items. However, to use assessments for treatment purposes necessitates the inclusion of dynamic risk factors (i.e., criminogenic needs). Research indicates that many dynamic risk factors (e.g., current drug abuse, associating with criminals) predict as well as static criminal history factors (e.g., number of prior convictions, arrested as a juvenile).

Offender risk instruments that almost wholly comprise static risk factors are referred to as *second generation risk assessments*. Risk instruments with a majority dynamic risk items are referred to as *third generation* or *risk/need assessment instruments*. These third-generation assessment instruments have three important features. First, the individual criminogenic needs measured by them and the instruments in their totality predict criminal behavior as well as second-generation assessments. The next two features reveal the advantages of third-generation risk instruments. Second, they identify criminogenic needs that can serve as targets for intervention. Third, because dynamic items represent the majority of factors assessed in third-generation instruments, the assessments can be used to monitor changes in the offender over time.

This last feature, offender monitoring, has been examined infrequently, and yet it offers important evidence for the value of assessing criminogenic needs. A good illustration of the potential dynamic nature of a third-generation offender risk/need instrument is the Level of Service Inventory-Revised. Approximately two thirds of the items in the Level of Service Inventory-Revised are dynamic, and the instrument assesses six of the seven criminogenic needs of the Central Eight (it does not assess APP). Table 2 presents two studies, the first from the United Kingdom and the second from the United States. Both studies administered the Level of Service Inventory-Revised to probationers at the beginning of supervision and approximately 1 year later. At the start of supervision, the probationers can be classified as low or high risk

Table 1 Mean Effect Size by Targeting Criminogenic and Noncriminogenic Needs

Need Area	Effect Size (r)
Criminogenic needs	
Procriminal attitudes	.21
Procriminal associates	.22
Antisocial personality pattern	.22
Family/marital	.29
School/work	.15
Substance abuse	.11
Leisure/recreation	.21
Noncriminogenic needs	
Little fear of punishment	-.05
Personal distress (e.g., anxiety, self-esteem)	.08
Physical activity for its own sake (e.g., boot camps)	.08
Increasing school/work ambition without learning opportunities	.08

Table 2 The Dynamic Validity of Risk/Need Offender Assessment: Two Illustrations

Study/Intake	Reassessment	
	Low Risk	High Risk
United Kingdom		
Low risk	29%	59%
High risk	54%	76%
United States		
Low risk	22%	46%
High risk	23%	33%

Note: Percent recidivism one year post re-assessment.

Source: Author.

(usually done by taking the median score to create the two categories). At reassessment, differences emerge as to who remains at their initial risk level and who changes in risk (either increasing or decreasing). The recidivism rates 1 year after the reassessment were then measured.

Examining the results from the United Kingdom study, one can see that low-risk offenders who remained at low risk 1 year later had a recidivism rate of 29%, but those who increased their risk level showed nearly double the recidivism rate (59%). High-risk offenders who remained at high risk at reassessment demonstrated a recidivism rate of 76%, while the offenders who were reassessed as at low risk had a lower rate of 54%. A similar trend is apparent in the American study.

In the two examples, as with other studies of this type, what is unclear is whether the changes in risk levels were due to treatment programming or natural life occurrences. For the changes to occur, there must have been a change in the criminogenic needs of the offenders. Perhaps some found meaningful employment and pro-social friends (a decrease in risk), and others may have lost their job and developed friendships with pro-criminal others (an increase in risk). The value of systematic reassessments of risk and criminogenic needs for those who supervise offenders is immensely important. It allows case managers to know in a structured manner whether their clients are improving and thus stay the course in the management plan or whether they are deteriorating which would require altering the supervision plans.

Generality of Criminogenic Needs

An important question is whether the criminogenic needs of the Central Eight apply only to one group of offenders or to a wide range of offenders. Most of the early research on criminogenic needs focuses on male offenders. Research has now been conducted on a number of criminal subpopulations, especially with respect to the predictive validity of criminogenic needs. There have been fewer studies on the effectiveness of targeting criminogenic needs in treatment among offender subpopulations, but there is enough to suggest that criminogenic needs are applicable to a broad range of offenders and circumstances.

Feminist scholars were the first to raise concerns over the validity of the criminogenic needs with women offenders. They argued two points. First, since the majority of research has been on men, applying the findings to women is suspect. Second, these scholars suggested that women have other needs that are specific to their unique life circumstances, and these should be considered in assessment and treatment (e.g., history of sexual, physical, and emotional victimization; trauma; unequal power relationship with partner). However, the research on risk assessments that measures the described criminogenic needs (education/employment, companions, substance abuse, etc.) appears to apply equally to women offenders. Studies investigating additional, women-specific needs are ongoing, but so far their results have been equivocal as to whether these needs provide additional information as far as the prediction of criminal behavior is concerned.

With respect to treatment, targeting the criminogenic needs of the Central Eight also appears to function similarly with women. Those treatment programs that address these criminogenic needs demonstrate reductions in recidivism for female offenders. Women offenders certainly have needs different from men, but the needs may not be criminogenic. Rather, the specific needs of women may actually be responsivity factors. Responsivity factors affect how treatment is delivered. For example, treatment providers may first have to address a woman's trauma from abuse in order to move forward with treatment for substance abuse.

Research supporting the generality of the criminogenic needs has been extended to youthful

offenders, aboriginal/indigenous offenders, and offenders with mental disorder. It remains to be seen whether the criminogenic needs will also apply to other groups (e.g., sex offenders). Although it appears that the criminogenic needs of the Central Eight have wide applicability, it is unclear whether the criminogenic needs are to be given equal weights among subpopulations of offenders. Certainly with young offenders, the empirical evidence is that education (rather than employment) and family (rather than marital) should be given more attention. As the research accumulates, researchers may find that APP is especially important for offenders with mental disorder, and for some women, family/marital relationships may be especially salient.

Final Thoughts

The concept of criminogenic needs has had a significant impact on correctional practice. Offender assessments routinely include measures of criminogenic needs and are reflected in third- (and fourth-) generation risk/need instruments. It is now known that there is a predictive relationship between targeting criminogenic needs in treatment and positive outcomes. However, most of the evidence is correlational, and there have been very few experimental evaluations that demonstrate a causal relationship. It also appears that criminogenic needs are relevant to a number of offender subpopulations. Future research will undoubtedly refine the concept and improve the understanding of the relative weights of the criminogenic needs to different offenders.

CRIMINOGENIC NEEDS, TARGETING

The concept of criminogenic needs is drawn from the Risk-Need-Responsivity (RNR) model, which was developed by correctional psychologists in response to the *nothing works* movement in correctional rehabilitation. The RNR model is composed of three principles: the Risk, Need, and Responsivity principles. According to the second principle (i.e., the Need principle), an intervention will be most effective at reducing criminal recidivism when it engages treatment targets that have

been found to have the strongest association with criminal behavior.

The RNR model identifies eight factors that have been found to have strong associations with criminal offending. Each of these factors has two components, a criminogenic risk and a criminogenic need. *Criminogenic risk* factors consist of dynamic and static sets of personal traits and characteristics that have been found to have strong statistical associations with criminal behavior. *Criminogenic needs* are the dynamic aspects of each criminogenic risk factor that, when addressed successfully in treatment, reduce the likelihood that a person will engage in future criminal activities. Criminogenic needs focus on the dynamic aspects of each criminogenic risk factor because these are the components of each risk factor that are changeable and thus able to be the target of treatment efforts. This entry defines criminogenic needs and provides an overview of the different types of criminogenic needs that can be targeted in treatment.

Central Eight Criminogenic Needs

Correctional research has found that interventions have the biggest impact on criminal offending when they target the criminogenic needs with the strongest association with criminal behavior. The criminogenic needs most strongly associated with criminal behavior are often referred to as the *Central Eight* criminogenic needs. These criminogenic needs include antisocial behavior, antisocial personality pattern, antisocial cognition, antisocial associates, family and marital circumstances, work and school, substance use, and leisure and recreation. This list of criminogenic needs shows that the term *antisocial* plays a prominent role in the description of criminogenic needs. However, in the RNR model, the term *antisocial* is not used to label people whose thoughts or behaviors have reached a point considered abnormal or pathological, nor is this term used to denote the presence of specific mental disorders. Rather, the RNR model recognizes that people's thoughts, feelings, and behaviors occur on a continuum and depend on the processes that a person uses to make sense of, and respond to, situations. The processes that people use to make meaning of, and respond to, social situations are a central component of criminogenic needs because these processes are often

the targets of treatment efforts. Therefore, in the RNR model, the term *antisocial* is used to denote processes that lead people to think, feel, and act in ways that are supportive of criminal behavior.

Major Criminogenic Needs

The *Big Four* are the four criminogenic needs with the strongest association with criminal behavior. Specifically, these four criminogenic needs encompass a subset of the Central Eight: antisocial behavior, antisocial personality pattern, antisocial cognition, and antisocial associates. In the RNR model, these four criminogenic needs are the central focus of interventions aimed at reducing criminal behavior because the strength of their relationship with criminal behavior suggests that they each have a potentially causal relationship with criminal behavior. Each of the Big Four criminogenic needs is described in more detail below.

Antisocial Behavior

Antisocial behavior involves situations where individuals engage in behavior that violates the law over long periods of time. This behavior generally begins at an early age and occurs across a number of different settings. The criminogenic need typically associated with this factor is purposefully engaging in risky situations, sometimes referred to as thrill-seeking behavior. In order to address this criminogenic need, interventions focus on helping individuals to develop prosocial (i.e., noncriminal) responses to risky situations and prosocial outlets for thrill-seeking behaviors.

Antisocial Personality Pattern

Antisocial personality pattern involves having a temperament (i.e., stable set of responses to the environment that are deeply engrained in a person's personality) that includes two facets: (1) low self-control combined with high stimulation-seeking and (2) negative emotionality. The criminogenic needs associated with this factor include aggression, irritability, anger, emotional callousness, and a sense of being mistreated. Interventions associated with this criminogenic need focus on developing impulse control, anger management skills, and problem-solving skills.

Antisocial Cognition

Antisocial cognition plays a central role in criminal behavior because thoughts exert a direct control over a person's actions. Therefore, the criminogenic needs associated with this factor include the thoughts, feelings, beliefs, and attitudes that are supportive of antisocial or criminal behavior. Interventions for this criminogenic need focus on reducing the use of thoughts, feelings, beliefs, and attitudes that support the decision to engage in criminal behavior and helping people to develop prosocial identities.

Antisocial Associates

Antisocial associates are individuals who are either engaged in, or supportive of, criminal behavior. Antisocial associates are closely related to antisocial cognitions in the RNR model because criminal behavior and the antisocial attitudes and beliefs that support this behavior are often learned and reinforced through interactions with other people. The criminogenic need associated with this factor is the time a person spends with individuals whose behavior and/or beliefs are supportive of criminal actions. Interventions to address this criminogenic need focus on limiting exposure to criminal associates and building connections with individuals who are supportive of prosocial behavior.

Moderate Criminogenic Needs

The four remaining criminogenic needs included in the Central Eight are family and marital circumstances, work and school, substance use, and leisure and recreation. These criminogenic needs are sometimes referred to as the *Moderate Four*, because each has a moderate association with criminal behavior. Whereas, in the RNR model, the criminogenic needs associated with the Big Four are believed to have a causal relationship with criminal behavior, the Moderate Four factors are not believed to have a direct or causal impact on criminal behavior. Collectively, the Moderate Four criminogenic needs focus on who people spend their time with and what they spend their time doing. Three of the criminogenic needs in this category involve aspects of the social environments where criminal behavior occurs (e.g., home,

school, work, and community). In the RNR model, social environments impact criminal behavior through the rewards and/or disincentives for criminal behavior that are embedded in these settings. The fourth criminogenic need included in the Moderate Four is substance use. Many might expect substance use to have a strong association with criminal behavior. However, alcohol and illegal drug abuse have inconsistent associations with criminal behavior, which suggests that the relationship between these activities and criminal behavior is not always as direct as might be expected. Each of the four criminogenic needs in this section is described in more detail below.

Family and Marital Circumstances

The relative importance of criminogenic needs associated with the family of origin or marital circumstances depends on the age and life circumstances of the offender. In reference to criminogenic needs, the key aspects of both relationship domains are the quality of interpersonal relationships between individuals (e.g., parent–child or partner–partner) and the expectations and rules related to how a person is expected to behave. Specific criminogenic needs include interpersonal relationships with high levels of conflict and low levels of mutual caring, respect, and interest in each other as well as breakdowns in monitoring and supervision of activities. Interventions that address these criminogenic needs focus on developing strong and consistent systems within relationships with key family members and significant others that minimize conflict and support prosocial activities and the development of prosocial identities.

School and Work

The criminogenic needs in these social settings again involve the quality of interpersonal relationships that individuals have within school or work settings. The criminogenic needs in these settings also include the level of involvement people have in their work and/or school and the amount of satisfaction they obtain from their efforts in this area of their lives. Interventions for criminogenic needs in this area focus on increasing people's connection to their work or school by engaging

strategies that improve their level of performance and involvement in their work and increasing the rewards and satisfaction they receive for their efforts.

Leisure and Recreation

The criminogenic needs for this factor involve the types of activities people engage in during their free time and how much satisfaction they gain from these activities. Interventions for this criminogenic need focus on increasing a person's level of involvement in prosocial, organized leisure activities and improving how people structure and use their free time.

Substance Use

The criminogenic needs for this factor include the misuse of alcohol and the use of illegal drugs. The RNR model does not provide specific guidance on clinical cutoffs or thresholds at which the use of substances becomes a problem. Rather, it focuses on points when these behaviors get a person into trouble with the law. Interventions to address these criminogenic needs include efforts to lower or eliminate the use of the problematic substance(s) and to reduce contact with people and places that encourage the use of problematic substances.

Minor Criminogenic Needs

There are a number of factors that have been found to have small associations with criminal behavior. The RNR model purports that the small statistical associations that have been found between factors (e.g., personal or emotional distress, mental illness, social class at birth, physical health issues, and seriousness of the index offense) are driven by many factors, some of which are unrelated to criminal behavior. In some cases, however, the relationship between minor risk factors, such as psychopathology, and criminal behavior may be driven by the relationship each one has with one of the Big Four criminogenic factors. In other cases, minor risk factors such as low verbal intelligence, gender, and ethnicity may represent responsivity issues that require consideration during the delivery of interventions that address one or more major criminogenic needs.

Targeting Criminogenic Needs in Treatment

The Need principle in the RNR model states that in order to reduce criminal behavior, criminogenic needs must be the central focus of treatment. A number of meta-analyses have found that correctional treatment services that target criminogenic needs associated with the Central Eight risk/need factors described earlier have the largest impact on criminal behavior. Furthermore, meta-analyses have consistently found that interventions targeting the Big Four criminogenic needs achieve the largest reductions in recidivism, with effect sizes of .20 or higher. This finding has led many to conclude that the Big Four criminogenic needs should be the central focus of correctional rehabilitation services that are focused on reducing criminal behavior.

CRIPS

The Crips is primarily, but not exclusively, an African American gang (i.e., a durable, street-oriented youth group whose involvement in illegal activity is

part of its group identity) formed in Los Angeles, California. What was once a single gang has evolved into a loosely connected network of individual sets. The gang is known for its members' affinity for the color blue and notorious for its ongoing feud with the Bloods, who associate with the color red. Crips gang members are implicated in murders, robberies, drug dealing, sex trafficking, and other serious crimes. This entry summarizes the history of the gang, its symbology, and its evolution over time, especially in relation to rivalry with the Bloods and reference to popular culture.

Origins and Early History

South-Central Los Angeles in the 1960s was an area that exemplified the bleakness of poor urban places. The Watts Riots of 1965 left an indelible mark on the city, and an entire generation of young Black men were searching for identity and respect, hanging out together in nascent *gangs* for protection in the violent streets. Undermined by the government and labeled a threat to national security, the Black Power movement and its various forms of self-advocacy were waning. It was out of the crisis of Black leadership that marked the end of the Civil Rights era that the Crips emerged.

In 1969, 15-year-old Raymond Washington, who had absorbed much of the Black Panther rhetoric of community control of neighborhoods, fashioned his own quasi-political organization in the Panther's militant image. Washington, who had a reputation for street fighting, assembled his friends to start a gang near his 76th Street home, initially called the *Baby Avenues* to pay homage to the Avenues, an older local gang. The Baby Avenues later renamed themselves the Avenue Cribs, shortened to simply Cribs, a play on the slang term for *home*, but also the group's youthful composition (i.e., a baby's bed).

Just how Cribs became Crips is disputed. Some argue that a drunken gang member repeatedly mispronounced the *b* as a *p* and it stuck. Others claim that because the gang's founding members would carry walking canes as an affectation, their victims would characterize their assailants as *crippled*. Still others say it was a typo in the *Los Angeles Sentinel* newspaper. Etymology aside, 2 years after Washington founded the Cribs on the city's east side, a young bodybuilder with an

affinity for street fighting named Stanley *Tookie* Williams was establishing himself across town on the west side. In 1971, Washington's East Side Crips and Williams' West Side Crips banded together to defend against other South Central gangs that were harassing them. In doing so, they created the Crips, a backronym for Community Revolution in Progress.

As the name implied, Washington and Williams intended to create a resistance movement for Black empowerment, but immaturity and inexperience meant that they failed to apply their vision of neighborhood protection into a broader progressive strategy. Instead, the group's membership became preoccupied with protecting themselves from marauding gangs in the community, and as is common with gangs, they became integrated through conflict.

The gang grew via friendship and kinship ties at Washington, Fremont, and Locke High Schools; Los Padrinos Juvenile Hall; and Fred Shaw or Bob Simmon's Home for Boys. It then expanded via a series of hostile takeovers of existing Los Angeles gangs. Washington, Williams, Mac Thomas (the leader of the Compton Crips), and Jimel Barnes (the leader of the Avalon Garden Crips) would venture into local neighborhoods and challenge the leaders of other gangs to one-on-one street fights. Although some gang bosses resisted losing their independence, this process resulted in most gangs agreeing to join the Crips, converting from small, independent cliques into subgroups or *sets* of the umbrella gang. Another round of gang mergers and acquisitions meant Crips sets soon outnumbered non-Crips gangs. By 1972, there were East Side Crips, West Side Crips, Compton Crips, Avalon Garden Crips, 43rd Street Crips, Harlem Crips, Hoover Crips, Inglewood Crips, and more, all emulating the territory-marking practices of the early Los Angeles Latino gangs.

However, rapid growth created problems for the fledgling gang. Long-standing enemies such as the Piru Street Boys and the Compton Crips were assumed to cooperate, for example, but grievances festered and individual personalities clashed. At the same time, non-Crips gangs, including the L. A. Brims, Athens Park Boys, the Bishops, and the Denver Lanes, sought an effective defense against Crips predation. In 1972, the Pirus split from the Crips. As a counterweight to Crips

supremacy, they formed a *blood* alliance with the other gangs, forming a new gang federation called *the Bloods*. The ensuing war between the Crips and the Bloods claimed more than 15,000 lives between 1972 and 2017.

Washington went to prison in 1974 for robbery, leaving Williams in charge of the gang. However, in 1976, Williams was injured in a drive-by shooting and later developed an addiction to phencyclidine (more commonly known as *PCP*). The gang was already too big to manage, and with Washington away and Williams preoccupied, the Crips dived deeper into criminal ventures. By the time Washington was released from prison in 1979, gunplay was more common than fistfighting, and young gang members were committing increasingly spectacular acts of violence in order to build their reputations.

Washington was opposed to gun violence and even attempted to reconcile the Crips and the Bloods, but soon discovered he had lost control of the gang he had cofounded. During a botched robbery in February 1979, Williams shot and killed the clerk at a 7-Eleven convenience store. Two weeks later, he killed a family of three during a robbery at a motel in South Central. Williams was ultimately convicted of four murders and sentenced to death. He rehabilitated inside prison, earning a Nobel Peace Prize nomination for his anti-gang advocacy. Still, in denying clemency for Williams, California Governor Arnold Schwarzenegger questioned whether Williams' redemption was complete and sincere, a case study in the stigma attached to gang membership and the suspicion that many gang members face when trying to disengage from gangs. Williams was executed by lethal injection in December 2005. Washington was killed in a drive-by shooting near his home in August 1979. He was 25 years old.

Migration and Mimicry

Ten years into their history, the two founding members of the Crips were gone. By 1983, the Crips seized upon the availability of illicit drugs, particularly crack cocaine, as a means of income. In poor urban areas hollowed out by deindustrialization and cutoff from economic opportunity by racial discrimination, crack provided one of few lucrative incomes for young Black men. Owing in

part to alliances made in the California state prisons, some Crips sets even began working directly with Mexican and Colombian drug cartels to traffic narcotics into the United States. Drug markets are self-enforced through violence, and at this time, production and possession of compact, inexpensive firearms were booming, with the so-called *Saturday Night Specials* (small caliber handguns of low quality) manufactured in California by the *Ring of Fire* gun companies. Turf wars turned especially violent, and gang-related homicides reached unprecedented highs.

During the 1980s and 1990s, Crips gang members also began migrating from Los Angeles to other U.S. cities to establish new drug markets and other criminal enterprises. This gave rise to Crips gang franchising or importation, whereby LA Crips would either colonize gangs in other locations or recruit local youth to establish a branch of the gang in an area previously untouched by gangs. Police crackdowns and tough new criminal justice sanctions on gangs followed, resulting in many Crips gang members being sent to prison. An alliance was subsequently formed between the Crips and the Folk Nation, a confederation of gangs originating from Chicago and the Midwest, as a means of protecting gang members incarcerated in state and federal correctional facilities. This, in turn, contributed to further gang proliferation. Imitation is the greatest form of flattery, and thanks to vivid depictions of the Crips in the gangster rap music of the N.W.A. and in Hollywood movies such as *Colors* in 1988, *Boyz n the Hood* in 1991, *South Central* in 1992, and *Menace II Society* in 1993, youth gangs across the United States began appropriating Crips style.

By the early 21st century, the Crips had outposts in some 40 states and upwards of 30,000 members, albeit differentially embedded in the gang and its activities. Crips sets also exist in Africa, Europe (e.g., the Netherlands and the United Kingdom), and Central America. In the age of global travel and the Internet, what were once distant, even metaphorical ties between Crips sets have, in some cases, become close, literal connections, with domestic and foreign gangs following and *friending* each other on social media and foreign gang members making pilgrimages to Los Angeles, which remains the Crips' stronghold.

Conflict and Consensus

It is a popular misconception that Crips feud only with the Bloods. In reality, many Crips sets remain independent and fiercely territorial, fighting among themselves. For example, the Rollin' 60s Neighborhood Crips from the Hyde Park area of South Los Angeles and the Eight-Tray Gangster Crips from 83rd Street have been rivals since 1979. This conflict has resulted in a more general dispute between *Gangster Crips* and *Neighborhood Crips* gang federations because, as gangs disseminated throughout Los Angeles and beyond, they divided into smaller and smaller sets and began to encroach on each other's territories.

In April 1992, just days before the Rodney King riots, the Crips and Bloods in the Watts neighborhood of Los Angeles convened in the Imperial Courts Project gym to negotiate a truce. Gang members were fatigued from decades of retaliatory violence. Assisted by football legend and activist Jim Brown and hip hop artists of the West Coast Rap All-Stars, they drafted a formal peace treaty modeled on the 1949 Armistice Agreements signed by Israel and Egypt, Lebanon, Jordan, and Syria. The gang ceasefire held for a number of years, and although shootings continued throughout the truce, violence declined to such an extent that, consistent with a nationwide crime drop, homicides in Los Angeles fell from over 1,000 in 1991 (a rate of 30 murders per 100,000 residents) to 550 in 1999 (15 per 100,000 residents). In 2016, there were 283 murders in Los Angeles (7 per 100,000 residents), but gang violence remains an intractable problem throughout California and the country.

Symbology

Gangs are known for their use of signals, which convey information understood by convention rather than by an intrinsic link with the message and are produced in a way that ensures coordination. Crips are no different. Large numbers of gang members frequent the same places and occupy relatively small geographical spaces. Thus, they rely on signals to identify one another. It is common knowledge that Crips identify with the color blue, which was inspired either by the colors of Washington High School or by the style of

Stanley Williams' friend Curtis *Buddha* Morrow. The Crips also represent left (vs. the Bloods who represent right), meaning they may roll up their left pant leg, wear their hat turned or tilted to the left, or hang a blue handkerchief out of their left back pocket.

Wearing blue and claiming Crips in the wrong context can be enough to incite violence. There are stories of youth wearing reversible jackets—Blood-red exterior with Crip-blue lining—to negotiate the risks inherent in walking between rival Bloods and Crips neighborhoods. This speaks to the fact that some signals, such as colored clothing, are easy to mimic. Since the 1990s, *gangster style* has permeated youth culture. Nongang youth wear the same blue baggy pants or Levi's jeans, baseball caps, basketball jerseys, and bandanas as their gang counterparts, lending some to rightly conclude that a Crips subculture exists beyond the gang. However, other signals are harder to fake. Hailing from Grape Street in the Watts section of Los Angeles, for example, convincingly marks someone as being at least friendly to the Crips, because Grape Street and the gang are synonymous. Interestingly, Grape Street Crips wear purple in addition to blue.

In their formative years, inspired by the style of early member Greg Davis, Crips carried a walking cane and wore khaki pants with the suspenders hanging down from the waistbands, Stacy Adams shoes, and brimmed hats. In the 1980s, Crips wore British Knights sport shoes because the company moniker B.K. was taken to stand for *Blood Killer*. Since the mid-1990s and the early 2000s, however, the use of colors and flamboyant clothing has waned since it attracts police attention and is one criterion for entry into a gang database.

Beyond clothing, graffiti and tattoos constitute a layered vocabulary for Crips members to communicate with one another. Popular Crips tattoos include a six-point Star of David (which pays homage to David Barksdale, the Chicago gang leader who founded the Black Disciples), six- and three-point crowns, and the Number 6 (meaning Crip up and Blood down), which all acknowledge the Crips' affiliation with the Folk Nation. Crips members refer each other as cousins (*Cuzz*) and in graffiti and other written correspondence. They will post their symbols, but invert, break, and/or cross out a rival gang or nation's symbol. Crips

will call Bloods derogatory terms such as *slobs* and *busters* and delete or change words containing the Letter B, owing to their association with the word *Blood*. If no word can reasonably be substituted, the Letter B will be crossed out to show disrespect. Sometimes, excessive use of the Letter C also occurs (e.g., “I’ll C right baCC”) to refrain from using the Letter B or the initials CK, which stand for *Crip Killer*.

For Crips, the *stacking* of complex hand symbols, such as sign language, is a gestural code to greet, confirm affiliation, disrespect rivals, and conduct business in secret. Crips are also known for the Crip Walk, or C-Walk, a dance step involving quick, intricate footwork that was first introduced into hip hop culture by Rapper WC (*Dub-C*). In the music video for the 2004 hit, “Drop it Like It’s Hot,” produced by Pharrell Williams, gangster rapper Snoop Dogg C-Walks and raps about having a blue flag hanging on the left side, another example of how Crips style permeates popular culture.

CRISIS INTERVENTION TEAMS

Crisis intervention teams (CITs) housed within police departments, sheriff’s offices, and other law enforcement entities represent an intersection of law enforcement and psychology to enable a proper law enforcement response to those with

mental health needs who are in crisis or need assistance. A CIT typically comprises specially trained police officers and/or mental health professionals. This entry reviews the origins of CITs, the different ways these teams are organized and utilized, and the training of their members and, through a number of case examples, highlights what these teams are able to accomplish as compared with a more typical police response to those in a mental health crisis.

Origins

Origins of CITs began in the late 1980s in Memphis, TN, where the police department and a number of local mental health agencies and universities collaborated in the creation of a police training program. Born in part by economic factors, an increasing homeless population with mental health issues experienced more and more run-ins with the police, yet the officers did not have adequate training to handle these types of situations. The different agencies began working together on the street, culminating in the creation of a specific training for police officers called the *Crisis Intervention Training*.

Training

The training of CIT officers typically entails increasing their understanding of psychiatric conditions such as schizophrenia and other psychotic disorders, bipolar disorder, depression, anxiety disorders such as post-traumatic stress disorder, and substance use disorders. Training also focuses on giving officers information and practical experience (typically through role-play exercises and through visits to local psychiatric care facilities), deescalating and intervening with people with these disorders. Officers are also given information about ways to address short-term needs of people in a mental health crisis (e.g., safety plans and no-harm contracts) as well as knowledge about local treatment and assistance options (e.g., programs that assist with life skills training, employment and housing opportunities, financial assistance, counseling, and medical aid).

These CIT training programs augment police academy training. Specifically, CIT officers are shown how to approach someone in a nonthreatening manner (as opposed to the authoritative

approach emphasized in basic police academy training) and how to listen empathetically, paraphrase, slow emotions down, help individuals move to a cognitive state, and provide understanding and support. These were the aspects of the Memphis Police Department's CIT program training that made it novel and effective. The implementation of the program was also unique in that many officers did not trust or understand the mental health community, but were now working closely and effectively by providing alternatives to jail for this population.

A benefit of having CIT-trained officers is a reduction in the number of use of force incidents. For instance, officers are trained in their police academy to take control of a situation upon arrival. This approach works very well in many situations but can be counterproductive in, for example, the case of a psychotic person. Recognizing the signs of psychosis and then taking a CIT approach to this person can often help deescalate these potentially lethal situations. CIT officers learn that the best approach, while maintaining officer safety, is to avoid crowding the individuals and overstimulating them with commands and physical presence. That authoritative approach can cause a psychotic person to become combative and thus provoke the use of force on the part of responding officers. Research on the effectiveness of CIT indicates that officers with this training often use less force and are more likely to refer individuals with psychiatric conditions to mental health services instead of taking them to jail.

Since the introduction of the Memphis Model of CIT, other departments have adopted similar trainings and programs. For example, Texas has a 40-hr Mental Health Police Officer certification for officers with over 2 years of law enforcement experience. Generally speaking, there are three different ways of implementing a CIT program. The first is the Memphis Model that trains officers in CIT and has made them respond to these types of calls for police service. The second method, the collaborative model, is to pair a police officer, preferably CIT-trained, with a mental health professional, to patrol together, responding to calls for service. The third method, often referred to as a Victims Services Unit or Crisis Team, trains mental health professionals to patrol and respond to police requests for assistance.

Additionally, CIT programs within law enforcement agencies do not always work only with mentally ill subjects. Other common uses of Victims Services Teams or Crisis Teams are a mental health response to assist people who have witnessed or experienced the death of a loved one (e.g., homicide, suicide, or by natural causes) and to assist victims of sexual assault, domestic violence, traffic accidents, suicidal persons, and other calls in which the presence of a mental health professional may be of benefit to those involved. A Victims Services Team or Crisis Team response to these types of calls often allows police officers to return to service more quickly, and those involved can receive support and referral information not commonly offered by police officers. Because this third method often allows officers to return to service, it is growing in popularity. Andrew Young, Jill Fuller, and Briana Riley researched this type of CIT program and found that both officers and victims benefit from the assistance, psychological support, and referral resources provided by these teams.

CIT programs are sometimes used to assist officers as well. A common example is a Crisis Incident Stress Management team comprising Crisis Incident Stress Management-trained officers, mental health professionals, and sometimes chaplains. This team assists officers after emotionally difficult or traumatic calls in order to give officers a safe place to decompress and process their experiences. Examples of calls traumatic for police officers are officer-involved shootings, extended or physically demanding operations, mass casualty incidents, the death of a child, and other events not commonly experienced by police officers. A Crisis Incident Stress Management team response may be as simple as a one-on-one chat with an officer after a difficult call or may take the form of a group meeting in which officers similarly exposed to a traumatic event can process that event together. This group meeting is often referred to as a psychological debriefing and guides officers through a specific seven-step protocol that helps them cognitively and emotionally process the event and offer support to one another.

Another example of law enforcement officers and mental health professionals working together in addressing crises is the use of psychological consultants on SWAT negotiating teams. Typically,

these consultants help assess the mental status of the subject holding hostages, who is barricaded, or who is threatening suicide, and provide negotiating and response strategies to the officers intervening with the subject in crisis.

Case Example 1

Officers were called to a local apartment complex regarding an individual brandishing a rifle at neighbors after an argument about an improperly parked vehicle. As responding officers approached the apartment, the individual pointed his rifle in the direction of officers as he turned to retreat into his apartment. Officers took up defensive and protected positions and then initiated a SWAT response. Through the course of negotiating with this individual, and interviewing family and friends, it came to light that this individual was a combat veteran and had been seeking assistance from the U.S. Department of Veterans Affairs for post-traumatic stress disorder. The SWAT negotiator on this call, who was CIT-trained and a combat veteran, was able to build rapport with the barricaded subject and to offer support, reassurance, understanding, and empathy. The officer then worked with this veteran on a safe plan for exiting his residence. Once taken into custody, a decision had to be made. Do officers arrest this man for aggravated assault (for pointing a rifle at responding police officers), or do they facilitate sending this man to an inpatient care facility because he is a danger to others due to his hypervigilance (being on guard, seeing threats everywhere, and responding automatically from his combat training), which is associated with post-traumatic stress disorder? In this case, due to the input from his family who was on scene, from the psychological consultant with the SWAT negotiating team, and due to his response to and compliance with the CIT officer, it was determined that remand to an inpatient facility would be the best way to resolve this situation.

Case Example 2

Officers are called because a man is on the roof of his house, naked, pointing toward the sky, and having an animated conversation with someone

who is not there. The police, the fire department, and ambulance service all arrive and receive no response from the man to their calls to him from ground level. The CIT officer on scene realizes that this man probably has a psychotic disorder (though hard to say if it is substance-induced or caused by a mental health condition) and seeks to ground this man in reality by asking the man to look at him, talk with him, and take a break from his conversation. After approximately 30 minutes of taking this approach and receiving no response, the CIT officer then claps his hands loudly and yells the man's name, which was given to the officer by a neighbor. The man breaks off from his conversation and is then able to engage the officer in answering a couple of questions before returning to his conversation with the air. After another 30 minutes of going back and forth between conversations with the air and the CIT officer, the man safely climbs down a ladder and gets into the waiting ambulance to be transported to the local emergency room for a physical and psychological assessment.

CITs began by trying to fill a need within law enforcement—bridging the gap between the basic training of police officers and the needs of people in crisis and/or with mental health conditions. Since its origin in Memphis, the use of CIT teams has broadened with the law enforcement community using mental health professionals in a variety of situations to provide for the needs of those in crisis and to mitigate the long-term effects of crisis. CIT teams are an important part of many law enforcement responses, especially those that may not solely be a criminal matter.

CYBERBULLYING

Cyberbullying refers to an aggressive, intentional, and harmful behavior willfully conducted by a group or individual toward a specific victim through the use of electronic messaging. When defining cyberbullying, many researchers begin with Dan Olweus's tenets of traditional bullying, which include intent to inflict harm, a power differential, and repetition. These aspects are present in cyberbullying, but it is conducted via computers, cell-phones, tablets, or other technological interfaces. Cyberbullies convey harmful messages through name-calling, rumor spreading, and abusive comments. Victims of cyberbullying experience an

array of physical, social, emotional, and cognitive issues that can extend into adulthood. Specifically, victims can experience a number of issues later in life, such as depression, anxiety disorders, and suicidal thoughts. Despite the relative dearth of research specifically on cyberbullying, this entry explores key aspects of this topic through the lens of traditional bullying and applies these concepts to the more recent online phenomenon. Beginning with an exploration of types of cyberbullying from the point of view of both victims and offenders, the entry then explores its psychological impacts and possible coping strategies and discusses prevention and intervention with an eye to legal issues surrounding this topic.

Overview of Cyberbullying Research

The impact of bullying has been studied for years across a number of disciplines; however, the impact of cyberbullying is less understood. As traditional bullying has largely occurred within the context of school, most bullying research presumes a physical or face-to-face context. Research is needed that focuses on bullying beyond school as the number of young people accessing the Internet increases and cyberbullying victimization increases concomitantly.

Cyberbullying research is currently conceptualized in varied ways, which has created inconsistencies across studies. One popular approach has been to define it broadly as bullying that occurs through electronic mediums, but this does not account for the differences between various electronic platforms. Other researchers have relied upon the work of Olweus who established the three main tenets of an individual experiencing bullying: (1) They are exposed to repeated negative actions, (2) these actions are inflicted on the individual from another person or persons, and (3) the individual has difficulty defending against these actions. Some individuals have extended this premise to cyberbullying by building upon the Olweus tenets and including the potential for one or more bullies.

Prevalence, Victims, Offenders, and Forms

The growth of Internet access has helped expand the number of potential cyberbullying offenders

and victims. It is estimated that over 77% of teenagers aged 12–17 years own a cellphone which allows the user to text message, e-mail, and access social networking sites. A survey in 2011 estimated that approximately 93% of children and adolescents use the Internet at least weekly, and 60% use it daily. There have been large variations in findings regarding the prevalence of cyberbullying victimization, with reported rates ranging from 11% to 72% but often hovering between 20% and 40% of middle- and high-school students.

The victims and offenders of cyberbullying are often teenagers or adolescents. Research is mixed regarding whether females or males are more likely to be involved in cyberbullying as victims or offenders. Cyberbullying affects individuals of all races. Further, individuals of the lesbian, gay, bisexual, and transgender (LGBT) community often have to deal with bullying. The National School Climate Survey in 2011 indicated that over 80% of LGBT youth had issues with bullying in regard to their sexual orientation, over 60% felt unsafe due to their sexual orientation, over 40% felt unsafe due to their gender identification, and over 30% did not go to school because they felt unsafe. The same survey indicated that LGBT youth are 3 times more likely to be victims of cyberbullying than other youth. Over 40% of LGBT youth reported experiencing cyberbullying, with 25% reporting that it occurred more than once, and over 50% indicated something unfavorable was said about them online. Over a third of LGBT youth also reported being sexually harassed online, and a fifth of LGBT youth reported receiving a harassing text message from other students.

Cyberbullying can take many forms. Young people use an array of devices with messaging capabilities. As teenagers have limited options where they can socialize outside of school, these social technologies have become integral avenues through which social connectivity can stretch beyond school hours and borders. Given the nature of online communication, cyberbullying perpetuates verbal bullying, and traditional intimidation is supplanted by humiliation, slander, and gossip. Cyberbullying often occurs through name-calling, rumor spreading, and abusive comments transmitted and conveyed through mediums such as instant messengers, social networking sites (e.g., Facebook, Twitter, Instagram), e-mail, and chat rooms. Age can play a role in the medium

through which the cyberbullying is conveyed, as older children and adolescents are more likely to be cyberbullied through social networking sites when compared to younger children.

Unique Nature of Cyberbullying

While similarities exist between traditional bullying and cyberbullying, the nature of the latter provides the potential for anonymity. Cyber-offenders can feel an added sense of security behind a computer screen or cellphone, making them less likely to follow societal pressures to act in a normative manner. Researchers have noted that cyberbullying is particularly malicious when offenders take steps to remain anonymous. Traditional bullying also tends to be characterized by a victim and bully, with few onlookers, while cyberbullying often features a large audience with ridicule that materializes quickly.

Implications

Implications and Ramifications for Victims

Youth victims of cyberbullying are treated in ways that negatively impact their physical, social, emotional, and cognitive functioning, as well as development and sense of well-being. Some researchers discovered that cyberbullying that uses pictures, video clips, or phone calls has a greater impact on victims than traditional forms of bullying. While traditional bullying victims are able to seek refuge after school, cyberbullying does not allow for this reprieve as bullies who possess access to the Internet are able to reach victims at all hours of the day. Research has found links between cyberbullying victimization and school difficulties (tardiness and truancy), suicidal ideation, eating disorders, chronic illness, depression, increased stress, social anxiety, and reduced self-esteem. In extreme cases, victims have used violence against bullies or committed suicide.

Psychological Impacts

Cyberbullying victims can experience a number of psychological issues as a result of their victimization. These include reports of feeling hurt, lonely, insecure, worried, embarrassed, anxious, angry, and socially inept. The consequences of

cyberbullying are not always uniform across genders. Male victims often report feeling vengeful and angry, while female victims tend more toward self-pity and depression. However, some researchers have found female victims reporting frustration and anger at higher rates than male victims; therefore, these gender-associated reactions to cyberbullying can vary. The impacts of transgender bullying must also be considered, as research has found that transsexual individuals are often victims. Research has discovered a link between transgender individuals being bullied and experiencing depression and suicidal thoughts.

Traditional bullying victims often fear returning to school where they may experience loneliness, humiliation, and insecurity. Researchers have noted the potential for cyberbullying victims to experience these feelings as well when considering the pain that can be endured when bullies use hateful terminology. Traditional bullying research has discovered that bullying takes its greatest toll on children who are repeatedly targeted, with victims being linked to poor mental health. These issues can extend into adulthood, as researchers have discovered that individuals bullied during childhood are at a higher risk when reaching adulthood of experiencing depression, anxiety disorders, and suicidal ideation.

Coping Strategies

Cognitive and behavioral coping strategies designed to reduce internal and external demands produced by stressful events can help mitigate the psychological, social, and physical issues produced by cyberbullying. Researchers have noted that an event itself is not harmful; rather, it is the evaluation of that event that gives the event context and meaning. Individuals who do not think they can change a stressful situation or who have limited resources to alter it often use an emotion-based form of coping. On the other hand, individuals who believe they have adequate resources are more likely to use problem-focused coping mechanisms.

Victims of cyberbullying are likely to view it as difficult to change. This may result in these individuals feeling like they must accept the situation and engage in emotion-focused coping such as anger, avoidance, and feeling helpless or depressed.

The longer the cyberbullying continues, the more likely the victim will view the situation as unchangeable and thus will engage in emotion-based coping strategies. Traditional bullying research indicates that victims utilizing problem-based coping strategies focused on taking action to prevent further bullying experience less health complaints than those who utilize an emotion-based coping strategy. Cyberbullying researchers have also found a link between the use of emotion-focused coping and increased risk of health complaints and depression as compared to victims who use problem-focused coping strategies.

Prevention and Intervention

As teachers connect with students daily, they are key agents in combatting cyberbullying. Studies have found varied support for school bullying prevention programs with some highlighting the importance of parents educating their children regarding proper Internet activity. Some schools partner with law enforcement agencies for information exchange purposes and to help bring formal charges against cyberbullies. Research supports school-level comprehensive programs to address bullying, while carefully supervising students, establishing rules and punishments for violations, and being strict about inappropriate behavior.

Legal Issues

Cyberbullying is difficult to monitor and regulate since the First Amendment to the U.S. Constitution protects most speech until the offender's behavior becomes harassment. School administrators can sanction traditional bullies since their actions usually occur at school. Cyberbullying often occurs outside of school; therefore, the investigation and interdiction of cyberbullying are less straightforward. Schools must develop clear policies regarding student online behavior and introduce learning exercises that enhance empathy and connect students with parents, school officials, and law enforcement. These efforts can reduce cyberbullying victimization and minimize the risk of reciprocal behavior, which could escalate to violence.

CYBERCRIME

Since the 1990s, cybercrime has become a matter of national priority and international policy. Research and teaching programs have proliferated alongside a large and sophisticated cybercrime security industry with investments being counted in the billions of dollars. Yet, while there is little disagreement that the problem exists, there is considerable debate as to what cybercrime exactly is and how to deal with it. This entry explores 10 key observations that can facilitate the understanding of its nature, the surrounding debates, and importantly the offenders.

Observations

The first observation is that *cybercrime takes place in a cyberspace*, an *imaginary* space created by the social reaction to the intersection of digital and network technologies and culturally shaped by social science fiction. Social behavior online has been transformed by digital and networked technologies across networks of communication, which has created behaviors that are global, informational, and distributed.

The second observation is that *cybercrimes are enabled by the same technologies that create cyberspace*. These same technologies have also transformed criminal behavior in much the same ways to make crime global, informational, and distributed. This virtual world not only has had a massive impact upon people's everyday lives, but it has also created new criminal opportunities causing victimizations that can have very real consequences for individuals. Originating in the 1980s' cyberpunk literature, the terms *cyberspace* and *cybercrime* cause much confusion, even conflict between different commentators. However, they have become so culturally embedded in the common parlance that it seems they are here to stay—despite attempts to avoid them by using the term *digital* or some other word instead.

The third observation is that *cybercrimes are becoming increasingly automated* as digital and networked technologies become more advanced and sophisticated. Networked and digital technologies do what other advanced technologies do: They deskill and then reskill labor—in this the crime labor that commits cybercrime (for offending is a form of labor). As with many aspects of ordinary work (labor) over time, technology and the ideas behind it have tended to separate out work tasks and automate them, usually to make them cheaper to perform and improve efficiency. In doing so, many skills have been absorbed by an automation process, but this deskilling has also created new skills to control the technology that controls those new processes (reskilling). The fact that one or two people can now control a whole criminal process that once required many people with specialist skill sets has profound implications for the understanding of the organization of cybercrime. In a rather cynical way, the Internet has effectively democratized crimes such as fraud

that were once seen as the crimes of the powerful and the privileged.

In a nutshell, networked and digital technologies have created an environment in which there is no longer any need for criminals to commit a large crime at a great risk to themselves because one person can commit many small crimes with lesser risk to himself or herself. Financial criminals can, for example, commit \$50 million low-risk thefts themselves from the comfort and safety of their own home, rather than a single \$50 million robbery with its complex collection of criminal skill sets and high levels of personal risk. If not a bank robbery, then criminals can commit a major hack, a distributed denial of service attack, a hate speech campaign, or suite of frauds; consider, for example, the case of the 17-year-old TalkTalk hacker who, with three others, allegedly hacked the TalkTalk database and stole the personal information of 1.2 million customers.

At the far end of this automation process, some malware can operate totally by itself (e.g., fake antivirus scams, ransomware), or it can run crime portals that can rent out bespoke malware via crimeware-as-a-service. In such circumstances, the scientific entry level required of cybercrime offenders has fallen and the technology effectively *disappears* because its operation becomes intuitive and offenders no longer require the programming skills that they once did. Another significant development has been the drop in the cost of technologies, which has dramatically reduced the start-up costs of crime, thus increasing the level of incentive. The impact of these transformations upon crime is that the average person can, in theory, commit many crimes simultaneously in ways not previously possible and on a global scale.

The fourth observation is that the term *cybercrime* addresses a series of quite different victim groups, which themselves proscribe different security debates. Although there may be similarities in crime type used, individual victims are quite different from business and organizational victims, who in turn are different from nation-state victims (national infrastructure). Each invokes different motivations, different offender groups and attack tactics, and different stakeholders and agencies. In addition, there is a need to separate the cybersecurity debates over risk and threats from the cybercrime debates (cybersecurity) over *actual* harms to individuals, businesses, and nation-states

(policing). These two sets of issues are often confused, sometimes deliberately, when in fact they each represent different actions. As in the off-line world, not all threats and risks manifest themselves as harms to the individual, and not all harms are crimes. But some do, which raises questions over how do we make sense of them—questions that are answered by the next three observations.

The fifth observation is that *cybercrime should be understood as a process of transformation rather than a thing or things*. One of the problems with contemporary explanations of cybercrime is that they attempt to buttonhole online actions into a definition, which never seems to explain satisfactorily the complete phenomenon—only parts of it at any one time. Instead of a definitional approach, David S. Hall has suggested that cybercrime really describes a transformation from one state (off-line) to another (online)—a process that is continuing into the future with the development of cloud technologies and the Internet of things. Using this approach, the multiple layers of cybercrime offending can be understood, not just in legal terms, but also in the different acts and different motivations.

The sixth observation, following on from the previous, is that *cybercrime disappears if you take away digital and networked technologies*. This is possibly the most significant of all observations when understanding cybercrime. If it does not disappear, then it is not a *true* cybercrime. By applying this transformation test, either scientifically or metaphorically, then the possibility arises that in addition to true cybercrimes there is a range of hybrids, which might explain some of the rather confusing definitions. It also helps explain what the *cyber-difference* is. This test also helps reflect upon how the crime was committed and the levels to which networked and digital technologies have impacted the criminal behavior.

This transformation test can be used to understand how crimes have been transformed in terms of their *mediation by technologies*. At the one end of the spectrum are *cyber-assisted* crimes that use the Internet in their organization, but which would still take place if the Internet were removed (e.g., a murderer searching *how to kill someone* or *dispose of the body* on a web browser). At the other end of the spectrum are *cyber-dependent* crimes, which are the spawn of the Internet, such as distributed denial of service attacks, spamming,

and piracy. If the Internet (networked technology) is taken away, then they simply disappear. In between the cyber-assisted and cyber-dependent crimes are various hybrid *cyber-enabled* crimes. These include most types of frauds and deception (but not exclusively) and are existing crimes in law but are given a global reach by the Internet, such as Ponzi and pyramid schemes. Take away the Internet, and these crimes still happen, but at a much more localized level, and they lose the global, informational, and distributed lift that is a characteristic of *cyber*.

The seventh observation is that *cybercrime offending has a number of different modus operandi* (objectives and intents). Therefore, *cybercrimes committed against the machine*, such as hacking and distributed denial of service attacks, need to be distinguished from *cybercrimes that use the machine*, such as frauds. Both of these also differ from *cybercrimes in the machine*, such as extreme pornography, hate speech, offensive imagery, and social networking-originated offenses. Yet, the distinction between them is rarely made in practice, even though the three types of modus operandi each relate to different bodies of law in most jurisdictions. Each of the three dimensions of cybercrime (the influence of technology, modus operandi, and victim group) has different implications for understanding the levels of victimization experienced but also the offenders and the way that they organize cybercrimes.

The eighth observation is that *the organization of cybercrime is very different from the organization of crime off-line*. While the media has tended to sensationalize cybercrime by linking it with mafia groups, the various literature on this issue suggests that the nature of cybercrime and conceptualizations of traditional organized crime groups are highly incompatible. Indeed, the literature points to forms of organization online that follow the distributed (networked), globalized, and informational patterns of cybercrime. So, one can talk about cyber-assisted forms of organization, whereby crime groups use technologies to assist their existing operations, including some traditional organized crime groups taking their existing areas of crime business online. There are also examples of cyber-enabled organization, whereby new groups of criminals use the Internet networks to organize themselves to commit financial crimes. They obtain personal information online (e.g.,

through phishing) and then give it to off-line money mules to monetarize the information. Take away the Internet, and they would commit the same crimes more locally and in much smaller volumes. Finally, there are cyber-dependent organized crime groups, who commune online and commit crimes online. They are likely never to have met and are often unlikely to know each other's identity other than by pseudonym. They are also very ephemeral, even fluid because they tend to be a collaboration of ideas. Their organization is disorganized by comparison with other criminal groups, and if the Internet were taken away, they would vanish.

The ninth observation is that *cybercrime creates challenges for the criminal justice system*. One of the most distinctive characteristics of true cybercrimes (cyber-dependent) is that they tend to be small-impact bulk victimizations. This means that they are often *de minimis non curat lex*, too small to prosecute, and police and the criminal justice system find it hard to act on them individually. Police can act only when a perpetrator is found, along with the aggregated proceeds of the crime as evidence. Because of their globalized nature, they are also jurisdictionally problematic, unless the perpetrator is found and the evidence is strong enough to warrant an extradition order if a treaty exists between the countries involved. Finally, there is also the need for policing expertise in cybercrime to be able to collect the relevant forensic evidence, build a case, and present it to the court for prosecution—and to instruct a specialist, such as a criminal psychologist, when needed. The final challenge is the *reassurance* problem in policing cybercrime. A culture of fear exists around cybercrime, which, for various reasons, exaggerates its impacts and causes a *reassurance gap* between the levels of security demanded by the public which policing agencies cannot deliver. This gap broadly shifts the policing focus toward answering those demands with highly publicized arrests and visible actions, which often shifts resources from essential cybercrime policing functions.

The tenth and final observation is that *cybercrime is not going to go away* as there is no silver bullet and the Internet cannot be switched off. All that can be done is to keep on top of developments, design out weaknesses, and mitigate issues as they arise. Furthermore, over the next 5–10 years, three key types of technological

developments could further challenge law enforcement and criminal psychologists. Mesh technologies will join with digital devices to develop lateral networks; self-deleting communications, such as TigerText or Snapchat, will eradicate evidence; and cryptocurrencies such as Bitcoin, Robocoin, Dogecoin, Litecoin, and especially Zerocoin, which claims to be anonymous, will create alternative value-exchange systems that could challenge the authority of banking systems. Collectively, these three technologies, further amplified in time by cloud technologies that will make more computing power available to criminals and the Internet of things, will expand the scope of devices connected to the Internet and also the volume of data flows, providing new criminal opportunities.

Conclusion

Since cybercrime is not going to go away, the most that can be done about it is to mitigate its impact as new forms arise and make it harder for offenders by using technology to identify offending, designing out criminal opportunity at the development stage, and educating and alerting potential victims of vulnerabilities. In doing so, however, the solutions are not always high-tech. On the one hand, cybercrimes are a product of the social reaction to new (criminal) opportunities created by networked and digital technologies, so some technical solutions are needed. However, on the other hand, there is a need to respond to the social impacts of cybercrime, especially where either young and other vulnerable people are not understanding the gravity of their own actions or their actions are being misunderstood by significant others (e.g., parents, teachers, police), particularly the transgressive behaviors that drift into serious crime without the offender leaving his or her bedroom.

CYBERSTALKING

Cyberstalking is a crime involving repeated pursuit or monitoring by electronic means. The form of this pursuit can be wide-ranging and involves unwanted attention through various forms of online or digital communication such as instant messages, social network posts, text messages, and e-mails. Often, cyberstalking is motivated by obsessive desires to get revenge, begin a relationship, or terrorize the victim in some manner. Cyberstalking has been a concern for Internet users, policy makers, and law enforcement personnel since the latter part of the 1990s. At that time, the extent of the problem was unknown, but it was clear that the widespread adoption of Internet technologies was providing stalkers with the tools to pursue, monitor, and communicate with victims remotely. Since then, researchers have developed a better understanding of the extent and nature of cyberstalking as a social problem. This entry reviews the scope of cyberstalking as well as the nature of cyberstalking victimization and perpetration, the theories used to explain its occurrences, and its consequences.

Comparing Cyberstalking and Offline Stalking

As the knowledge base around cyberstalking has developed, its definition relative to offline stalking

has been debated. There is a definitional overlap between cyberstalking and offline stalking, but also potential for divergence. In terms of their similarities, cyberstalking and stalking both involve a course of conduct directed at a specific person. A course of conduct can include a number of repeated and unwanted behaviors, such as following, spying on, e-mailing, texting, or calling a victim. Further, like offline stalking, the online pursuit behaviors are considered repeated when they occur two or more times. Most definitions of stalking also include reference to the emotional distress—or fear—experienced by the victim as a consequence of the stalker's pursuit. Unlike offline stalking definitions, definitions of cyberstalking are less consistent in incorporating the victim's emotional distress as a criterion in identifying the behavior as a crime. This is a point of some debate, as conceptually the fear criterion differentiates cyberstalking from other forms of online victimization, such as harassment or cyberbullying. These definitional points aside, cyberstalking is often considered a type or method of stalking.

Extent

Estimates of the extent of cyberstalking have mostly been generated through victimization surveys. While these survey estimates differ, they generally agree that cyberstalking is experienced by a substantial number of individuals. The 2006 National Crime Victimization Survey provides the most methodologically rigorous estimate of cyberstalking victimization in a general population and suggests that 26% of victims of stalking in the United States also experience cyberstalking. Yet, it is noteworthy that this estimate views cyberstalking in conjunction with offline stalking, which has an established definitional criterion related to the harm (i.e., emotional distress) experienced by victims. Stand-alone estimates of cyberstalking victimization that do not include this criterion have produced estimates as high as 40%. This highlights the importance of how cyberstalking victimization is conceptualized as either including or excluding the victim's fear as a consequence of the stalker's course of conduct. Available evidence also suggests that the prevalence of cyberstalking is higher among certain populations—particularly among college students.

With respect to the perpetration of cyberstalking, it is more difficult to gauge its extent due to a lack of data sources. However, small-scale studies of high school and college student samples suggest that approximately 5% of those populations have engaged in online pursuit behaviors against other students. Further, research investigating the extent of cybercrime has estimated that cyberstalking accounts for approximately 40% of all cybercrime incidents.

Victimization

Research into cyberstalking victimization has revealed patterns in characteristics of victims as well as risk factors for victimization. Based on the available data, victims of cyberstalking appear to be principally female and young (i.e., 24 years on average). Other personal characteristics of victims, such as race and sexual orientation, have also been investigated, but to a lesser degree, and regular patterns in these characteristics have not emerged. In terms of situational characteristics, research has consistently found that individuals are more often cyberstalked by someone they know (e.g., boyfriend, coworker) than by others, but there also are reported cases of cyberstalking by strangers. Beyond this sort of descriptive information about cyberstalking victims, research has also reported that certain victim behaviors—for example, online social network activity—may facilitate opportunities for victimization.

Perpetration

The perpetration of cyberstalking has been less studied than cyberstalking victimization, but there are also patterns in personal characteristics and criminal behaviors among cyberstalkers. While a profile of cyberstalkers does not exist, research data suggest that they are predominantly male, young (e.g., in their 20s or 30s), and White. In many cases, cyberstalkers and victims also had some kind of relationship (e.g., friend, romantic partner) prior to the offender's pursuit of the victim.

With respect to this pursuit, evidence suggests that there are also apparent patterns in the tactics used by cyberstalkers. According to the National Crime Victimization Survey, the most common methods of cyberstalking involve repeated

interpersonal communication through e-mail, instant messages, or blogs/bulletin boards. However, it should be pointed out that the pace of technological change potentially alters the landscape within which cyberstalking occurs; therefore, these tactics may have changed since these data were collected.

Cyberstalking can also involve electronic monitoring, wherein the cyberstalker uses global positioning systems, listening devices, cameras, or computer spyware to observe and/or pursue the victim. Approximately 8% of stalking incidents in the United States involve electronic monitoring in some form according to the National Crime Victimization Survey. It is also apparent that there is an overlap between offline stalking and cyberstalking, although the extent of this overlap has not been widely researched.

Theories of Cyberstalking

Theoretical explanations of cyberstalking are still developing, but current theories from fields such as criminology, victimology, and psychology provide initial insights into the roots of victimization and perpetration. In the case of the former, the opportunity perspective suggests that individuals are victimized when motivated offenders encounter criminal opportunities. Applied to cyberstalking, these criminal opportunities may be created when a victim's online routine activities make them vulnerable to an offender's pursuit behaviors. As an example, the type of information an individual posts on an online social network, or the degree to which this information is made public, may facilitate opportunities for victimization. Research also has reported that the victim's level of self-control may indirectly create such opportunities.

With respect to the perpetration of cyberstalking, little research has directly addressed the mechanisms behind online pursuit behaviors. Yet, early research findings suggest that existing theories of criminality, such as control theory, neutralization theory, rational choice theory, and social learning theory, have some utility in explaining cyberstalking perpetration. Within this body of research, traits such as low self-control, shame, anger, and insecurity have been linked to pursuit behaviors.

Consequences of Cyberstalking

Although there have been few studies into the consequences of cyberstalking victimization, research from the offline stalking literature as well as anecdotal evidence suggests that cyberstalking can have severe consequences for victims. The obsessive and repetitive nature of the pursuit behaviors coupled with the potential for anonymity in online forums can lead victims to experience a number of emotional and psychological symptoms—particularly fear. Scholars have investigated the nature of fear of crime quite extensively, and as it pertains to online victimization, research suggests that a number of factors are antecedents to fear. For example, gender, the relationship between the victim and the offender, and the perceived risk of further victimization have all been linked to fear of online victimization. Besides fear, victims of cyberstalking also may experience feelings of anxiety, depression, anger, frustration, insomnia, helplessness, or other forms of emotional distress. This suggests that the emotional consequences of cyberstalking are similar to those of offline stalking victimization.

D

DA DANGEROUS OFFENDER LEGISLATION

Each country, state, province, region, and jurisdiction handle dangerous offenders in different ways. Over the past several decades, there has been a move on the part of some governments to *get tough on crime* by imposing mandatory minimum and indefinite sentences on offenders thought to be at a high risk for new crimes. This entry focuses on two examples of this movement in the Western world: the civil commitment laws that were adopted in several U.S. jurisdictions and the dangerous offender legislation adopted nationwide in Canada.

The difference between committal legislation in Canada and that in the United States is that in Canada, if offenders are considered dangerous, they are sentenced to indefinite terms of incarceration at the beginning of their sentences, whereas in the United States, a small group of sexual offenders can be civilly committed at sentence expiry. Presumably, while incarcerated, these individuals could participate in treatment programs that are designed to equip them for a parole release to the community while paying due regard to the safety of the public. However, direct comparisons between Canada and the United States are not yet possible due to the lack of a single, criminal national database in the United States.

U.S. Approach

In the United States, decisions to confine offenders indefinitely are made at sentence expiry using civil

commitment laws. For the most part, these measures are brought against offenders who have histories of convictions or sexual crimes. In the United States, civil commitment actions are brought against sexual offenders who are thought to be mentally ill in some manner and are thought to require further treatment. Offenders can be incarcerated indefinitely or until decision-makers determine that they have been successfully treated and could be released without compromising the safety of the public.

Canadian Approach

In Canada, the primary dangerous offender legislation is Section 753 of the Criminal Code of Canada, which was passed in October 1977. This legislation was intended to restrain offenders whose behavior was unlikely to be inhibited by *normal standards* of behavioral restraint. Offenders so designated are sentenced to indeterminate periods of incarceration or until such time as their risk to reoffend could be safely managed in the community. In August 1997, the legislation was revised so that it became possible for an offender so designated to receive a determinate sentence, although most received indeterminate sentences (life). The majority of these offenders (71.5%) were sentenced for at least one sexual offense.

The 1997 legislation was amended again in 2008. This amendment requires the prosecutor to apply for the dangerous offender designation if the offender was convicted of a designated (personal injury) offense and had two prior

convictions for a designated offense for which the offender received a sentence of at least 2 years. This means that prosecutors have to apply for dangerous offender designation in cases where such an application might not have been considered prior to the amendment. In addition, the law also requires the accused to prove he or she should not be declared dangerous rather than requiring the prosecution to establish dangerousness at the sentencing stage.

The number of individuals declared dangerous offenders under Section 753 increased by 20% between 2004 and 2008 (the end of year to the end of year). In the same 5-year period, there was only an 8% increase in the total offender population. Not only is the number of individuals who are designated as dangerous offenders increasing, but so is the proportion of First Nations people who receive an indeterminate sentence as dangerous offenders. For example, in Saskatchewan, 82% of offenders sentenced as dangerous offenders as of 2016 were First Nations people although they represent only about 14% of the provincial population. While perhaps not as dramatic, a similar pattern exists in the rest of Canada. Although the number of indeterminately incarcerated offenders continues to grow, there is no available evidence to indicate that this has resulted in increased public safety. In fact, the low release rates make it unlikely that there are sufficient numbers of parole releases to properly study long-term release practices.

In the case of offenders serving determinate and indeterminate sentences, the responsibility for the decision to release the offender rests with the Canadian National Parole Board. Theoretically, the National Parole Board would release an individual when he or she would no longer represent an unmanageable risk to the public. However, it has been found that there is a negligible effect on parole on imprisonment rates because so few offenders receive parole that there is almost no effect of parole on the number of people incarcerated. According to Anthony Doob, Cheryl Marie Webster, and Allan Manson, the low parole rates in Canada suggest that abolishing parole altogether would have limited effect on the number of incarcerated offenders. This is also true for offenders who were declared dangerous and received indeterminate sentences.

A study by Terry Nicholaichuk and colleagues (2013) investigated whether the presumed intent of the legislation was actually translated into sentencing practice. They examined the correctional careers of indeterminately sentenced dangerous offenders, the majority of whom were sentenced for sexual crimes. For the group of 193 men designated as dangerous offenders between 1977 and 1997, the average length of their incarceration was 17.7 years. For the 31 offenders from the group who were conditionally released, the mean number of years of incarceration prior to their release was 14.4 years. Only one individual who was designated a dangerous offender after 1997, and who reached his parole eligibility date, was released. He was incarcerated for 9.8 years prior to his transfer to a minimum-security facility. Finally, of the 31 released dangerous offenders, only two reoffended, but neither with a sexual offense.

Although the intent of the dangerous offender or civil commitment legislation seems reasonable when taken at face value, it appears that this intent may not be reflected in actual practice. At least in Canada, the sentence appears to be applied randomly. *Dangerousness* is a legal term rather than the one based on research data. Therefore, the sentence does not necessarily reflect the offender's empirically derived estimate of risk. Being declared a dangerous offender with an indeterminate sentence overwhelmingly predicts that the individual will die in prison regardless of his level of risk or current age. Although this may satisfy the *get tough on crime* advocates, it seems to be a policy that disproportionately penalizes some minority groups (e.g., Indigenous minorities).

DEATH PENALTY

The death penalty, also known as *capital punishment*, is a government-imposed sanction by which a person is executed for committing an illegal offense. The United States is the only country in the Western world to retain this form of punishment. Consequently, it is the subject of much controversy. China, Iran, Saudi Arabia, Iraq, and the United States are responsible for the majority of the world's executions. Most countries have abolished the death penalty.

This entry discusses key statistics surrounding the death penalty, major legal rulings relating to capital punishment, the capital trial process, capital jury decision-making, the psychological impact of imprisonment on death row, and wrongful convictions.

Methods of Execution

The most common international methods of execution are electrocution, lethal injection, the gas chamber, the firing squad, and hanging. Other methods include shooting, beheading, stoning, and falling from a lethal height.

In the United States, lethal injection is the primary method of execution for all states that retain the death penalty. Alternative methods include electrocution, the gas chamber, the firing squad, and hanging.

Offenses Punishable by Execution

In the United States, the death penalty is almost exclusively reserved for the first-degree murder crime. Some states have other capital offenses, such as treason, aggravated kidnapping, drug trafficking, aircraft hijacking, and espionage.

However, as of 2017, no inmates are on death row for such crimes.

In like fashion, the federal government authorizes the death penalty for espionage; treason; trafficking large quantities of drugs; and attempting, authorizing, or advising the killing of any officer, juror, or witness in cases involving a continuous criminal enterprise, regardless of whether or not the killing actually occurs. However, as of 2017, no prisoners are on death row for such offenses.

Death Penalty in the United States

As of 2017, 31 states and the federal government had the death penalty. There were approximately 2,800 prisoners on death rows across the country. California, Florida, Texas, and Alabama had the largest death row populations. The death penalty is arbitrarily applied. Specifically, it is more likely to be sought, and obtained, in cases involving defendants who are male, Black, and economically disadvantaged.

Executions in the United States

Nearly 1,500 prisoners have been executed in the United States since 1976. Executions reached an all-time high in 1999, when 98 death row inmates were executed. The number of executions has fallen consistently since that year.

Region

The southern region of the United States is responsible for over 80% of the nation's executions. Texas, Oklahoma, Virginia, and Florida have executed the most inmates in the United States.

Gender

Over 99% of the executed death row prisoners were men. Only 16 women have been executed between 1976 and 2017.

Race

Statistically, more Caucasian death row inmates have been executed. However, when compared to Black and Hispanic prisoners, Black death row

prisoners who kill White victims were nearly 10 times more likely to be executed than White death row prisoners convicted of killing Black victims.

Average Time Spent on Death Row

The average time spent on death rows across the United States has steadily increased since the 1970s. In 2017, death row prisoners spend approximately 16 years on death row before execution, exoneration, or commutation of their sentences to life imprisonment.

Aging Death Row Population

The death row population in the United States has aged significantly. The number of death row inmates 65 years and over has quadrupled in recent years. Although some prisoners are on death row because they committed offenses late in life, the lengthy appellate process is primarily responsible for the aging of prisoners under the sentence of death.

Death Row Phenomenon and Death Row Syndrome

The living conditions on death rows across the United States have been the subject of sharp debate. Called the *death row phenomenon*, inmates are forced to endure a bleak, hopeless environment for years, if not decades, living with uncertainty regarding when—or if—they will ever be executed.

Prisoners on death row are kept in solitary confinement for over 23 hours per day inside small, windowless cells. They are allowed outside recreation a few days per week. However, this time consists of exercise alone inside a concrete or wired enclosure. Any time death row inmates are allowed out of their cells, they are handcuffed and shackled. Sometimes *black boxes* made of hard plastic that offer additional restriction of movement are placed over their handcuffs. Death row inmates also lack basic comforts such as climate control, regular access to reading material, and contact with loved ones. The living conditions on death row can cause *death row syndrome*, or depression, anxiety, and psychosis

so severe that it can cause inmates to become suicidal or forgo their appeals.

Major U.S. Supreme Court Rulings

In the 1960s, the U.S. Supreme Court began adjusting the way the death penalty was implemented. In the 2000s, the Court narrowed the range of offenses for which people were eligible to be executed. This resulted in a series of rulings that impacted the way capital defendants were sentenced.

Witherspoon v. Illinois

In 1968, the Court held that jurors could be excluded from capital jury service if they could never impose a death sentence. However, merely being opposed to the death penalty was not sufficient to excuse a juror for cause.

Furman v. Georgia

In 1972, the Court ruled that the death penalty was *cruel and unusual punishment* due to its arbitrary application. As a result, the death penalty was unconstitutional and commuted all death row prisoners' sentences to life imprisonment.

Gregg v. Georgia

In 1976, the Court reversed its position, holding that the death penalty did not violate the Eighth Amendment prohibition against cruel and unusual punishment. The ruling also provided three procedural reforms by bifurcating capital trials into verdict and penalty phases, initiating automatic appellate reviews for defendants under the sentence of death, and beginning proportionality reviews on the premise that the death penalty is reserved for only *the worst of the worst* offenses.

Wainwright v. Witt

In 1985, the Court redefined the standard for death qualification by broadening the definition of excludable jurors. Specifically, in order to be *death-qualified* (eligible to sit on a capital jury), a person's beliefs about the death penalty cannot be so strong that they would prevent or substantially impair his or her ability to render an impartial decision.

Lockhart v. McCree

In 1986, the American Psychological Association submitted an amicus brief to the Court, summarizing the body of research that suggested the process of death qualification resulted in jurors who were prone to convict and sentence the defendant to death. However, the Court held that the process did not violate defendants' Sixth and Fourteenth Amendment rights and deemed death qualification to be constitutional.

Atkins v. Virginia

In this 2002 case, individuals with intellectual disabilities were prohibited from facing execution. However, they are still eligible to serve sentences of life imprisonment without the possibility of parole.

Roper v. Simmons

In 2005, the Court excluded juveniles from facing the death penalty. However, they were still eligible to serve sentences of life imprisonment without the possibility of parole.

Uttecht v. Brown

In 2007, the Court again narrowed the pool of death-qualified jurors by ruling that a *venireperson*, or prospective juror, could be excluded for cause if his or her beliefs about the death penalty are unclear. In addition, a juror could be excluded from capital jury service if the individual cannot consider both legal penalties (either the death penalty or life in prison without the possibility of parole) as appropriate forms of punishment.

Hall v. Florida

In 2014, the Court concluded that solely using a defendant's intelligence quotient score to render a determination of intellectual disability was fundamentally flawed due to the error inherent in any measurement. Consequently, the Court ruled that evidence of adaptive functioning should be considered when rendering a decision regarding the defendant's intellectual disability.

Attitudes Toward the Death Penalty

Although a majority of Americans are in favor of capital punishment, this support dropped consistently since the mid-1990s. Those who support it tend to do so because they focus on retribution. People who are opposed to the death penalty tend to cite the chance of executing an innocent person, lack of deterrence to crime, cost, and arbitrary application as the most common reasons for their beliefs.

Death Qualification

Death qualification is the part of jury selection during which prospective jurors are questioned regarding their beliefs about the death penalty. Although the theoretical goal of death qualification is to seat an impartial jury that is comprised of jurors who are able to consider both the death penalty and life in prison without the possibility of parole as legitimate forms of punishment, in reality, this is not what occurs. Rather, the process of death qualification systematically excludes more prospective jurors who are opposed to the death penalty than those who feel that the death penalty is the only appropriate sanction for the offense of first-degree murder. As a result, the remaining jurors tend to be demographically, dispositionally, attitudinally, and behaviorally homogeneous, resulting in a panel that is pro-prosecution and anti-defendant process.

Demographic Differences

Death-qualified jurors are more likely than jurors who are not death-qualified to be Caucasian and male. They are also more likely to be middle class and high school educated.

Dispositional Differences

Death-qualified jurors are more disposed than their excludable counterparts to have a low need for cognition, meaning that they do not tend to engage in effortful cognitive activities. Death-qualified jurors are also more likely to hold a high belief in a just world, which is the cognitive bias that a person's actions are inherently inclined to bring appropriate consequences, with good behaviors being rewarded and bad behaviors being

punished. They are more prone to have an internal locus of control or believe that they are in control of the events affecting their lives. Death-qualified jurors are more likely to be legal authoritarians, believing that individual freedom is subordinate to the power of the government.

Attitudinal Differences

Death-qualified jurors tend to endorse aggravating circumstances and dismiss mitigating circumstances. They are more likely than jurors who are not death-qualified to support the death penalty as it relates to mentally ill, juvenile, elderly, and physically disabled defendants. Death-qualified jurors are also more disposed to believe in eyewitness identification and junk science. They are also less likely to support the insanity defense.

Behavioral Differences

When compared to their excludable counterparts, death-qualified jurors are more likely to be pro-conviction and pro-death. Specifically, they are more likely to find defendants guilty. Death-qualified jurors are also more prone to vote in favor of the death sentence.

Process Effects

The process of death qualification is also responsible for the biasing effects inherent in this portion of jury selection. During death qualification, venirepersons are repeatedly questioned regarding their beliefs about the death penalty. This can occur over hours, days, or weeks. The process is done either individually or in small or large groups. It can also occur in a sequestered or public manner. In essence, the potential panel is discussing the punishment long before it is relevant. This brings their focus off the presumption of innocence and onto post-conviction events. The lengthy and repetitive nature of the process is desensitizing, causing the significance of the decision to vote on whether someone lives or dies to lose its impact. Potential jurors are asked to publicly state their attitudes about the death penalty, which can enhance their commitment to a particular position, thus making a later change of opinion more difficult.

Aggravating and Mitigating Circumstances

Aggravating circumstances are reasons to impose the death penalty. Aggravators must be proven beyond a reasonable doubt and are limited by statute. Ultimately, the judge determines which arguments the jury will hear. Although each state has different aggravating circumstances, there is a tremendous overlap. Aggravators can include the crime being cold, calculated, and premeditated; the offense being especially heinous, atrocious, or cruel; the capital defendant's future dangerousness; and the victim being aged under 12 years.

Mitigating circumstances are reasons to impose a sentence of less than death, which is usually life imprisonment without the possibility of parole. Mitigators must be proven by the preponderance of the evidence and are unlimited in nature. Ultimately, the judge determines which arguments the jury will hear, although the rules of evidence are more lenient than with aggravating circumstances. Each state has different mitigating circumstances listed as examples in their respective statutes. However, there is a significant overlap between statutes, and all states allow additional mitigating circumstances to be presented in court. Mitigators can include no significant history of prior criminal history, an offense committed while the defendant was under the influence of an extreme mental or emotional disturbance, the age of the defendant at the time of the crime, and any other factors in the defendant's background that would mitigate against the imposition of the death penalty.

Capital Jury Decision-Making

Capital juries have the formidable responsibility of determining the life or death of another human being. As a result, capital jury decision-making is a complex process that is impacted by a wide variety of factors.

Unanimity

In all states that retain the death penalty, the 12-person capital jury is required to make a unanimous decision in the verdict (guilt) phase. In 2017, a unanimous decision is required in the penalty (sentencing) phase in all but one state. Specifically, only Alabama requires a supermajority (10–2 vote) to impose the death penalty.

Unanimous juries are more likely to have robust deliberations, jurors expressing confidence in their verdicts, and feel that justice was administered. The unanimity requirement increases the length of deliberations and decreases death sentences.

Instructional Incomprehension

Each state and the federal government have different capital jury instructions. Although there can be some differences depending on the jurisdiction, all capital jury instructions are complicated. As a result, they are frequently misunderstood, and misapplied, by capital jurors. The lack of comprehension appears to be differential in nature. Specifically, capital jurors appear to be more confused about mitigating circumstances than aggravating circumstances. This misunderstanding can lead capital jurors to incorrectly categorize mitigators as aggravators. This incomprehension also has a racial component. Caucasian capital jurors are more likely to sentence Black defendants to death when there is a general lack of understanding regarding jury instructions.

Instructional understanding is significantly enhanced when psycholinguistically improved instructions are utilized. A few states have attempted to modify their jury instructions to enhance comprehension.

Capital Pretrial Publicity

Most capital cases receive a significant amount of pretrial publicity. An analysis of the pretrial publicity associated with criminal cases has demonstrated that it is overwhelmingly pro-prosecution. This is likely due to the fact that media sources tend to be law enforcement and state attorneys' offices.

The media's goal is to engage readers. When covering a capital defendant's case, this is primarily accomplished through sensationalistic, overly simplistic stories designed to shock and horrify. The capital defendant is often portrayed as *all bad*, without any redeeming qualities. The victim is portrayed as *all good*, with only positive attributes. Unfortunately, neither of the aforementioned is an accurate portrayal of the complex dynamics that are inherent in every capital case.

The capital defendant is often described in derogatory, subhuman terms. The media often

accomplish this by giving the defendant a nickname more appropriate for a horror movie. News stories also tend to focus on aggravating factors, such as defendant's prior criminal history and offense-specific details. A confession, if provided, is often recounted in detail. The crime scene, described as graphically as possible, is frequently a front-page news. Even innocuous events such as a capital defendant asserting his or her Fifth Amendment right against self-incrimination are reported in an unfavorable light, such as "refusing to cooperate with law enforcement."

As a result, prospective jurors who have been exposed to pretrial publicity are biased against the defendant before they walk into the courthouse. This knowledge will have a significant effect on any capital trial because people are unable to force themselves to forget or ignore what they have learned. Consequently, judicial admonitions for venirepersons to put aside their preexisting knowledge about the case are completely ineffective. Rather, the only solutions to counteracting exposure to pretrial publicity are change of venue (moving the trial to another jurisdiction), importing the jury (bringing in jurors from another jurisdiction), and thorough, comprehensive voir dire (jury selection) that includes pretrial surveys and individual, sequestered questioning of venirepersons.

Innocence and the Death Penalty

In the United States, over 150 people have been exonerated after receiving sentences condemning them to death. The most common causes of wrongful convictions are police and prosecution misconduct, eyewitness misidentification, false confessions, junk science, unreliable informant testimony, and ineffective assistance of counsel.

DESISTANCE

Desistance is generally defined as ceasing to commit any future criminal activities—as such, it is more specific than crime reduction. However, the topic of desistance in the study of criminology and criminal justice is characterized by a lack of agreement on how it is defined among those studying it. Thus, desistance is explored in numerous studies, but all using different predictor variables to capture its results.

After briefly reviewing the history of the study of desistance in the field of criminal justice and desistance theory, this entry reviews some of the theories that provide a foundation for how to explain desistance as well as the desistance process. Also reviewed in this entry are several factors that with some debate have been found to be relative to the desistance discussion. Last, this entry discusses some issues associated with measuring desistance.

Brief History

Beginning around the 1980s, scholars and practitioners in the field of criminal justice started looking at desistance from crime through a different lens. In addition to viewing the crime phenomena from a standpoint of its effects, researchers began to study what contributed to desistance.

Research found that although there is no agreed-upon definition for desistance and each person's reasons for ceasing criminal behavior differ, there are common individual factors that contribute to desistance. In addition, research indicated that many offenders eventually become tired of the punitive aspects of crime, which then becomes a driving force to their desistance. From such research emerged desistance theory, which in a very broad sense is a description of the social and cultural aspects of life that transform a person's willingness to participate in crime.

However, desistance theory had a difficult time gaining traction in the study of criminology due to a large empirical focus on offending during teenage years. In 2001, John H. Laub and Robert J. Sampson conducted a longitudinal study that included the life course perspective on desistance in order to better understand how crime cessation works. This perspective claims there is variation in criminal behavior—that is, in the onset, maintenance, and desistance. Laub and Sampson further explained that there are different factors that influence desistance at the age of 18 years, as opposed to at the age of 30. This approach was pioneering because it took into consideration an entire life's work of crime, not just simply a maintenance phase in which criminal activity is likely to be at its height.

Theories and the Desistance Process

Scholars working to answer the questions surrounding crime and desistance have relied on several theories as being fundamental to understanding leaving the criminal lifestyle. Much of what has been written regarding desistance is strongly entrenched in social control theory, emphasizing self-control and a reduction in antisocial behavior. As such, social control theory is central to the theory of desistance and its relevance to the life course perspective of offending. To explain desistance over the course of life, Laub and Sampson used marriage as one variable to predict this process. Using social control theory as a foundation, they stated that while marriage itself does not increase constraint over time, it should lead to a reduction in criminal behavior. Marriage is just one variable viewed as prosocial that has been used by researchers to study desistance. Family, school, peers, education, work, and community have all been identified as potentially significant factors as well.

With social control theory placing an emphasis on self-control, the cognitive aspect of crime desistance involves a realization of the participants' own role in the desistance process. Psychological engagement by any individual wishing to leave a criminal lifestyle must be present in order for this process to continue. In this view, it can be understood why only studying teenagers and their desistance from crime may be problematic. Many scholars would contest that there is a certain maturity process that takes place for people over time. Applied to criminology and desistance, this is often referred to as a *stake in conformity*. Responsibilities such as education, employment, relationships, and children contribute to the development of a stake in conformity.

Desistance has often been thought of in opposition to recidivism. Correctional settings such as jails and prisons and probation and parole departments are judged by their abilities to cut down on recidivism among offenders. Although this may not always be a fair assessment of correctional effectiveness, it is a way to measure desistance with an active offender population. Traditional practices of corrections, both institutional and in the community, focused on punishment and retributive-based management. A shift

in paradigm over time to a more rehabilitative approach has signaled a change in philosophy. Rehabilitation as it pertains to desistance does not strictly deal with treating an offender for a substance abuse or other mental health-related issue, but also the process by which a person sustains his or her nonoffending behavior over time. This desistance process is about stopping criminal activity and refraining from offending.

The final piece of the desistance puzzle process, as outlined by D. Richard Laws and Tony Ward, has to do with community reintegration. Reentry practices have been shown as necessary to the success of parolees in the community. One of the catch phrases of the popular self-help group, Alcoholics Anonymous, is that people must change their people, places, and things if they wish to remain sober. Much can be said about the validity of this statement in relation to desisting from crime. Denis C. Bracken, Lawrence Deane, and Larry Morrisette recognized the influence that an individual's society can have over moving away from crime. With regard to reentry practices, support for prosocial living is crucial. The process of reintegration falls largely on those people, places, and activities by which an offender can engage, and an important area is the availability of resources such as finances. Prosocial services such as transportation, housing, clothing, food, education, and employment are all made easier to obtain when a financial burden is lifted.

Factors Relevant to Desistance

The desistance research has examined several factors relevant to leaving the criminal lifestyle. This section reviews just a few of these: the maturation process, type of offenses, amount of crime and duration of desistance, and gender.

Maturation Process

Literature throughout criminology has shown that leaving a criminal lifestyle takes place at later ages for adults. One of the most often cited reasons associated with this is maturity. Maturity and its measureable variables can be defined in a number of ways. Michael Rocque, Chad Posick, and Ray Paternoster studied such demographic measurements as social bonds in adulthood, sex, race,

socioeconomic status, grades, peer delinquency, and parental attachment. These predictors can be found in much of the desistance research. What is often debated, however, is the age at which desistance begins to set in.

In one study involving 29 *desisters* in Canada, an age range of 21–71 years was discovered among the sample. This large range is unlikely to represent an average of those desisting from criminal activity across a broad spectrum; however, it does take into consideration a cessation period of between 2 and 9 years for the offenders in the study. Laub and Sampson offered a more indirect answer to this question by stating that the benefits of their study are the strongest for ages of 28–31 years, which is a positive predictor of desistance from crime. Although there is generally no agreed-upon age at which criminal activity can be said to cease, most scholars believe that the defining of adulthood (18–21 years) begins this process.

Types of Offenses

Studies have shown that offenders who participate in violent crime have a more difficult time desisting than those who do not. Few people would argue that the commission of an armed robbery is the same in criminal nature to the underage consumption of alcohol. A classic example of this would be gang members. Armon Tamatea argued that gang members have an especially difficult time desisting from their lives of crime due to the highly violent nature of the acts that they commit, as well as continuing in the culture well beyond adolescence. Gang membership as a barrier to desistance is also attributable to its promotion of antisocial ideals, its overall structure, the number of offenses that are committed by its members, and its consideration as a primary criminogenic factor overall. These traits are more of an exception than a rule in the criminal world, although the prevalence of violent crime in society makes it noteworthy to this discussion.

Amount of Crime and Duration of Desistance

Research has looked at not only the amount of crime that has been committed leading up to a period of desistance but also the duration the

offender desists for over time. Barry Vaughan addressed both of these questions by determining that a high degree of intrinsic value must be placed on reflection as well as on weighing the choices in front of offenders. Reflection allows for individual consideration for what has been previously done, and the weighing of choices pits options against how a person wishes to live his or her life.

Other literature dealt with these issues separately, questioning whether desistance is different for a single act of crime versus for multiple instances of crime. It is vital to flesh out not only this distinction but also what may be referred to as *hybrid offending*. Hybrid offending pertains to offenders who may have a history of property crimes and then exhibit sexual offending behavior, as an example.

Gender

Men and women offend differently in a variety of different ways. The rate at which they commit crimes, the types of crimes that they commit, the age at which they first offend, and when they desist from criminal activities all differ between the two sexes. Peggy C. Giordano, Stephen A. Cernkovich, and Jennifer L. Rudolph indicated that, particularly with adolescents, females are not as likely as their male counterparts to be delinquent. This presents an empirical challenge to studying desistance among genders as they are not comparable in the rates at which they offend. This argument is underscored by the fact that few longitudinal studies exist that include large numbers of delinquent females. Research in this area of desistance may be lacking, but there are several conclusions that have been drawn to distinguish between the two. Laub and Sampson admitted that females were more likely to desist from crime than males, although the factors associated with those decisions were the same. With respect specifically to female offenders and the type of crime committed, the field would benefit from more research being conducted.

Measuring Desistance

Measuring desistance has been problematic, as several areas present difficulty. For example, the

amount of crime, discussed in the previous section on relevant factors, presents a measurement problem that is not easily solved. Much debate abounds regarding the measurement of time between crimes, arguably the definition of desistance. For instance, Isabelle F. Dufour, Renée Brassard, and Joane Martel maintained that it is impossible to determine when an offender's criminal career is over.

Another problematic area in measuring desistance is differentiating between those activities that are criminal and those that are deviant in nature. Much like debates surrounding the definition of what constitutes recidivism, desistance experiences a similar snafu. Those debating the pillars of recidivism struggle with defining it as a new charge, a new arrest, or a criminal act committed but not caught doing. Laub and Sampson made a striking comparison that desistance could be jeopardized by acts such as alcohol consumption, having children out of wedlock, government financial dependence, gambling, and congregation with individuals of ill repute.

These measurement issues stress the importance of conceptualizing and operationalizing desistance in research projects.

DETERRENCE

Deterrence is the omission or curtailment of crime out of fear of legal punishment. People may refrain entirely from committing crime out of fear of legal punishment, or they may only curtail or restrict their criminal behavior because of it. An example of curtailment would be a burglar taking a break from burglary believing that repetition will eventually result in being caught. There are three ways deterrence can be considered a psychological theory. First, the terms *fear* and *perceived punishments*, which are central to deterrence theory, are psychological variables. Second, deterrence is compatible with learning and rational choice theories, which are psychological theories. Third, other psychological variables, such as morality, self-control, and emotion, may condition the deterrent effects of perceived punishments.

Background

Put briefly, the logic of deterrence is that legal punishments deter crime to the extent that people perceive the punishments as certain, severe, and swift. A complexity, however, is the distinction between specific and general deterrence. Whereas specific deterrence involves direct experience with legal punishment, including avoidance of legal punishment, general deterrence involves indirect experience with punishment and punishment avoidance through observing or somehow learning about the punishment experiences of others. If a judge sentences a robber to prison in the belief that the imprisonment will deter him from

committing more robberies after his release, the judge's goal is specific deterrence. If the judge sentences the robber to prison to serve as an example thereby deterring others from committing robberies, the judge's goal is general deterrence.

Importance of Fear and Perceived Punishments in Criminal Deterrence

The terms *fear* and *perceived punishments* are necessary to distinguish deterrence from other reasons people refrain from committing crime. For example, some people may believe that a particular type of behavior is illegal based on their knowledge of instances of others' behavior that have resulted in legal punishment. It does not follow, however, that they refrain from the behavior because they fear legal punishment, or they perceive that legal punishments are certain, severe, and swift. Instead, they may refrain out of what Jack P. Gibbs calls an *uncritical obedience to law*. It is also possible that some people refrain from committing crime out of habit rather than deterrence. Legal punishment may in the beginning deter some people from committing crime, but their behavior may ultimately become habituated. Franklin Zimring and Gordon Hawkins (1973) offer an example:

The threat of punishment may cause a man to refrain from speeding on his way to work. After a while, however, . . . he may have developed the habit of driving at a certain speed, and this habit provides additional insulation against future law violation. (p. 85)

Deterrence, Learning, and Rational Choice

Deterrence researchers have long recognized the compatibility of deterrence with learning and rational choice theories, which are psychological theories. For example, the notion of specific deterrence corresponds with experiential learning, and the notion of general deterrence corresponds with vicarious learning. Learning theory suggests that any behavior is likely to be a consequence of both experiential and vicarious learning, so it follows that the amount of crime in any population will likely be a consequence of both specific and general deterrence.

Both deterrence and learning theories emphasize the importance of rewards as well as

punishments. Deterrence researchers have tended to focus on punishments more than rewards probably because the criminal law itself focuses on punishments. Rewards, however, are also relevant.

Jeremy Bentham, who was an early deterrence theorist, saw happiness as a composite of maximizing pleasures (rewards) and minimizing pains (punishments) and believed that people will choose behaviors that are more rewarding than punishing. According to Cesare Beccaria, another early deterrence theorist, a way to increase the deterrent effects of legal punishment was to make crime less rewarding than conformity to the law.

Like deterrence and learning theories, rational choice theory emphasizes that people weigh the rewards and punishments of alternative behaviors. Applied to crime, the logic is that a person will commit crime to the extent to which the rewards for crime (weighted by the probability of obtaining the rewards) outweigh the punishments (or costs) for crime (weighted by the probabilities of obtaining the punishments). The rewards and punishments for conformity to the law (noncrime) are also relevant, but they are not often included (at least not explicitly included) in studies of rational choice and crime. The rewards and punishments for noncrime are treated as opportunity costs or, as Ross L. Matsueda and colleagues explain, "opportunities forgone by virtue of crime."

This means that rewards for crime may be important to deterrence by conditioning the deterrent effects of legal punishment. Charles R. Tittle and Ekaterina V. Botchkovar referred to *criminal motivations* rather than rewards for crime, but they conceived of criminal motivations in the same terms as any conceptualization of criminal rewards—the pleasure or attractiveness of crime. The motivation measures varied considerably among people, and they were strongly associated with projections of future criminal behavior (the greater the motivation, the greater the projected future criminal behavior). Moreover, there was evidence that deterrence was more likely among those with greater motivation to commit crime.

Conditional Effects of Deterrence

The rewards of crime are one psychological variable that may condition the deterrent effects of

legal punishment. Morality, self-control, and emotion are other psychological variables that have received attention in deterrence research.

Morality and Deterrence

With morality, the question is whether the deterrent effects of legal punishment depend on a person's moral beliefs, and there are two competing predictions. According to Tittle (1980),

it is plausible . . . that those few morally committed individuals who do contemplate deviance might be especially deterred because the possibility of sanctions would dramatize the inconsistency of the contemplated deviance with their moral commitment. (p. 18)

Deterrence, then, should be more likely among people with strong moral beliefs. In 1971, Zimring predicted the opposite: Deterrence should be greater among people with weak moral beliefs. For them, fear of legal punishment may be the only barrier to committing crime.

The evidence is markedly mixed. In a 1978 study of Arizona high school students, Gary F. Jensen, Maynard L. Erickson, and Jack P. Gibbs found no evidence that deterrence was dependent on morality. Neither did Harold G. Grasmick and Donald E. Green in a sample of adults in 1980. In 2011, Lieven Pauwels, Frank Weerman, Gerben Bruinsma, and Wim Bernasco found, in a study of Dutch adolescents, that morality did not condition the deterrent effects of perceived punishments on total offending. For assault and vandalism, however, the evidence was consistent with Tittle's prediction. Deterrence was more likely among people who strongly disapproved of assault and vandalism. This may have been because adolescents with strong moral beliefs would feel guilt or shame if legally punished for crime.

Other studies have also found greater deterrent effects among people with strong moral beliefs. For example, Owen Gallupe and Stephen W. Baron (2014) concluded from a study of street youths in Canada that the greater the perceived certainty of getting caught, the less the likelihood of soft drug use but only "at high . . . [and] not low levels of morality" (p. 295). Similarly, in 2016, Alex R. Piquero, Jeffrey A. Bouffard, Nicole L.

Piquero, and Jessica M. Craig concluded from a study of incarcerated felons that high perceived certainty had a deterrent effect on the likelihood of driving drunk among those with strong but not weak moral beliefs about crime.

Still other studies have found evidence consistent with Zimring's prediction that legal punishments will be greater deterrents among people with weak moral beliefs. In 1976, Matthew Silberman found that

the threat of punishment is a more important factor in preventing the individual who is less morally committed from becoming involved in serious criminal activities than in preventing those who are more morally committed from becoming so involved, since the latter are not inclined to become seriously involved anyhow. (p. 455)

Similar findings have also been reported. In a 2015 study of Swedish youths, Robert Svensson also found that the "effect of deterrence on offending is . . . greater for individuals with lower levels of morality" (p. 12).

Self-Control and Deterrence

With self-control, the question is whether the deterrent effects of legal punishment depend on a person's self-control, and there are three predictions. The first prediction is that people with low self-control will be just as deterrable as those with high self-control. A second prediction is that people with high self-control will be less deterrable because they are predisposed to conform to the law anyhow. A third prediction is that people with high self-control will be more deterrable because compared to people with low self-control, they place more weight on the long-term consequences of their behavior.

As with morality and deterrence, the evidence is mixed, though it tends to favor the first prediction. For example, John K. Cochran, Valentina Aleksa, and Beth A. Sanders (2008) found that "the effects of perceived sanction threats on college students' self-reported academic dishonesty did not vary by their level of . . . self-control" (pp. 461–462). Although the study pertained to cheating rather than crime, the findings were consistent with other

studies of deterrence and crime. For example, Gallupe and Baron in their 2014 Canadian study found that deterrence did not depend on whether street youths had low or high self-control. Similar findings were reported by Tittle and Botchkovar in their study of Russian adults and Pauwels and colleagues in their study of Dutch adolescents. In contrast, Wright, Avshalom Caspi, Terrie E. Moffitt, and Ray Paternoster in a 2004 longitudinal study in New Zealand reported findings consistent with the second prediction—there were weaker deterrent effects of perceived punishments on self-reported crime among people with high self-control. In 1994, Daniel S. Nagin and Raymond Paternoster found, consistent with the third prediction, that U.S. college students with high self-control were more deterred from committing crimes by the perceived risks of arrest than were those with low self-control.

Emotion and Deterrence

Zimring and Hawkins argued that people may be less deterrable when they are emotionally aroused. For example, when angry, people may not think about the future consequences of their behavior and focus instead on their anger and what is responsible for it. There is surprisingly little research on emotion and deterrence. In 2004, Stephanie Carmichael and Alex R. Piquero hypothesized that “under high perceived emotional arousal [anger], perceived costs [of legal punishment] will be less influential . . . , while under low/moderate perceived emotional arousal, perceived costs will be more influential” (pp. 379–380). To test their hypothesis, they administered a survey to a sample of undergraduate students who were asked to read a hypothetical scenario in which two antagonists became angry and one eventually assaulted the other. The students were then asked to estimate the likelihood they would commit assault in the same situation, how angry they would be in the situation, and their perception of the certainty (likelihood) of being caught and arrested if they committed assault. Consistent with their hypothesis, a high perceived certainty of legal punishment did not significantly reduce the likelihood of assault among students with strong anger. Contrary to their hypothesis, however, the perceived certainty

of punishment was also unrelated to the likelihood of assault among students with low or moderate anger.

In a related study, Jeffrey A. Bouffard randomly assigned male undergraduate students to view sexually arousing videos/photographs (treatment) or sexually neutral photographs (control). He then asked the students to read a hypothetical date scenario that included the potential for sexual coercion and report the likelihood they would use several sexually coercive tactics themselves on their dates (e.g., getting a woman drunk in order to have sex with her). The students were also asked their perceptions of the legal and nonlegal costs and benefits of these tactics. Although Bouffard did not examine whether the effects of the costs and benefits on the likelihood of sexual coercion depended on a person’s sexual arousal, he reported two relevant findings. First, sexual arousal increased the likelihood of sexual coercion. Second, aroused students reported that the benefits were more important than the costs in deciding whether to use sexual coercion, which would make it difficult for legal punishments to deter.

DETERRENCE EFFECTS OF ADJUDICATING AND SENTENCING JUVENILE OFFENDERS AS ADULTS

All states in the United States have laws providing that, under certain circumstances, serious or repeat juvenile offenders can be adjudicated and/or sentenced as adults. In addition to serving the retributive need for punishment, these laws were enacted largely in the hopes that they would deter juvenile crime and reduce recidivism among youthful offenders. Since 1990, empirical studies have been conducted to ascertain whether these laws are having the intended effect of reducing recidivism. The studies inform legal policies and practices on handling serious and chronic juvenile offenders.

Types of State Transfer Laws

The so-called juvenile *transfer* or *waiver* laws differ in the circumstances under which juvenile offenders may or must be transferred from the juvenile system to be adjudicated and/or sentenced as adults, the procedural mechanisms for doing so, and whether doing so involves the juvenile court, the criminal court, or both courts. Most states permit or require transfer of juveniles aged 14 and older who commit murder, violent felonies, or certain other crimes if the juvenile also has a prior record. A few states permit juveniles of a certain age to be transferred for any crime.

Transfer can be accomplished in one of four ways, with most states having at least two of these mechanisms in place, with statutes specifying which types of offenders are to be transferred under which of the following mechanisms:

- *Automatic or legislative transfer statutes* provide that juveniles of a certain minimum age charged with particular serious offenses and who meet other statutory criteria are automatically adjudicated in the criminal court.

- *Judicial transfer statutes* provide that the juvenile court judge decides whether a juvenile who meets the statutory criteria for possible transfer will be transferred. In addition to providing age and offense criteria, the statute lays out a list of discretionary factors the judge is to consider in deciding whether to transfer, such as the juvenile's amenability to rehabilitation in the juvenile system, his or her criminal sophistication, and whether transfer is necessary to ensure public safety.
- *Prosecutorial transfer statutes* are just like judicial transfer laws, except that it is the prosecutor who decides whether to charge the juvenile in juvenile court or criminal court, again based on statutorily enumerated factors.
- *Reverse transfer statutes* provide that the cases of juveniles who meet certain age and offense criteria begin in the criminal court, but the criminal court judge then decides (based on statutorily enumerated factors) whether the case should be transferred *down* to the juvenile court.

These mechanisms pertain to adjudication—whether the juvenile is tried in the juvenile or criminal court.

With respect to sentencing, usually the same court that tries a juvenile also sentences him or her, but an increasing number of states have enacted *blended sentencing* laws. Some laws allow juvenile court judges to impose adult criminal sentences, while others allow criminal court judges to impose juvenile dispositions. Still others provide a true blending in sentencing whereby the juvenile or criminal court judge imposes both a juvenile and an adult sentence: The juvenile sentence is served while the juvenile is still a youth, but then a criminal sentence is triggered once the juvenile reaches age 18–21, either automatically or if the juvenile fails to successfully complete the juvenile disposition and court terms.

Purpose and Impact of Transfer Laws

Transfer laws were enacted to achieve the goals of retribution and/or deterrence (general or specific). Retribution is the goal of imposing just punishment and is based on the notion that serious juvenile offenders deserve to be punished as adults.

Deterrence is the goal of preventing crime and comes in two forms: general deterrence (detering would-be offenders from committing crimes in the first place) and specific deterrence (preventing recidivism—i.e., deterring offenders from reoffending). The empirical research on general deterrence is more limited and more conflicting than that on specific deterrence, but it tends to suggest that transfer laws fail to produce any general deterrent effect. This entry focuses on the issue of specific deterrence: Does transferring a juvenile to criminal court for adjudication and sentencing reduce the likelihood that he or she will recidivate? Another goal of transfer is very practical. Older juveniles, who are about to *age out* of the jurisdiction of the juvenile justice system when they turn 18, are often transferred simply to ensure an adequate length of incarceration past the age of majority.

At present, there is not accurate data on the number of juvenile offenders transferred to the criminal justice system, but it is estimated that each year more than 100,000 juveniles are adjudicated in U.S. criminal courts. The impact on the child of being tried or sentenced as an adult can be substantial. A felony conviction carries with it the loss of a greater number of civil rights and privileges than does a juvenile conviction, having negative repercussions for later employment as well as reintegration into community life. Importantly, when juveniles convicted as adults are then placed in adult prisons, they usually receive far fewer age-appropriate treatment and rehabilitative services than they would have received in the juvenile justice system. Juveniles incarcerated in adult facilities are also at substantially greater risk of physical and sexual assault from adult inmates as well as suicide, and they learn and model criminal mores from the experienced adult criminals in the facility.

Empirical Studies on the Specific Deterrent Effects of Transfer Laws

Between 1990, when the first empirical study of the specific deterrent effects of transfer was conducted, and 2017, there have been 10 published studies on this issue:

- Five studies found that transfer *increased* overall recidivism.

- Three studies found *no effect*, one way or the other, of transfer on overall recidivism.
- Two studies found that transfer *reduced* overall recidivism. These are the two most recent studies and also arguably the most methodologically sophisticated studies.
- With respect to violent felonies specifically, two of the studies found that transfer increased recidivism and one found it had no effect.

The 10 studies were conducted in seven states (Arizona, Florida, Minnesota, New York, New Jersey, Pennsylvania, and Washington) having differing laws on transfer. They compared the recidivism outcomes of juveniles retained in the juvenile system against the recidivism of those transferred to the criminal justice system. The studies used different techniques for measuring recidivism and different follow-up periods (from 18 months to 8 years after adjudication). The studies also used differing methodologies to control for selection bias due to differences between the transferred and retained groups of juveniles.

Although fairly sophisticated, these studies are substantially limited by the fact that although they attempt, either through statistical controls or the matching of pairs of transferred and retained juveniles, to account for differences relating to recidivism risk between juveniles in the transferred versus retained comparison groups, no study can measure all possible differences. Many studies have not included, for example, measures of juveniles' attitudes, gang involvement, relevant family and community risk and protective factors for reoffending, or the sentences imposed and rehabilitative treatments received. For example, one recent study, which reanalyzed the data from an earlier study finding that transfer increased recidivism, found that transfer did not actually increase recidivism once the sentence type was taken into account in the analysis. Consider also that another recent study found that transferred versus retained youth differ significantly in their calculations of the costs and rewards of crime and punishment and their exposure to violence, yet such factors were not taken into account in previous studies.

A meta-analysis that pooled the 10 studies together (for a total sample size of 12,325 youths) and then performed a statistical analysis on the pooled sample found that transfer does not have

an effect one way or the other on recidivism overall; yet in some circumstances, it decreases recidivism and in others transfer increases it. The meta-analysis was sophisticated, using a technique that accounted for unpublished studies that may have found results differing from the known published studies. It also accounted for differences between the studies (study design, sample size, offense types, transfer law, recidivism measures, and follow-up time). This meta-analysis provides the most robust bottom-line conclusions that can be drawn from the existing body of empirical studies on the specific deterrent effects of transfer and that bottom line is that one size does not fit all with respect to transfer. Although overall transfer does not appear to impact recidivism, that high-level conclusion is fairly unstable in that it appears subject to many exceptions—in a significant number of cases, transfer increases recidivism, and in a significant number of cases, it decreases it.

Explanations for the Findings

The research indicates that transfer often fails to decrease recidivism and sometimes actually increases it. It is not known for sure why this is the case, but experts have identified the following possible explanations:

- Juveniles incarcerated in adult facilities receive fewer age-appropriate rehabilitative and treatment services than they would have received in juvenile facilities.
- Juveniles incarcerated in adult facilities learn criminal mores and behavior from adult inmates who often victimize them.
- Juveniles having an adult felony conviction face increased stigmatization and collateral negative consequences of a felony conviction that limit their educational, career, and community reintegration prospects.
- Research shows that juveniles who are adjudicated as adults feel a sense of resentment and unfairness at having been tried as an adult, and this resentment may fuel their criminal trajectory by further ingraining in them the self-image of *criminal*.

The counter-rehabilitative effects of transfer may be due not to transfer itself (i.e., the child

being adjudicated as an adult) but rather to the sentence imposed by the criminal court. Research suggests that the increases in recidivism often seen among those transferred are due to the negative effects of incarceration in adult prisons and the nongraduated sentences meted out by the criminal court. If a juvenile should be adjudicated as an adult for retributive reasons, if doing so is necessary to ensure public safety (i.e., to keep the offender confined past the age of majority), or if all previous graduated juvenile sanctions have failed, then perhaps this may be done without increasing the likelihood of recidivism so long as the court imposes an incremental sentence that provides sufficient age-appropriate rehabilitative treatments in juvenile facilities.

Implications for Juvenile or Criminal Justice Policy and Practice

Several implications for juvenile or criminal justice policy and practice arise from the existing research. Following from the research findings, judges and prosecutors should base their discretionary transfer decisions not on a “one size fits all” approach but on a detailed evaluation of the juvenile’s offense history, rehabilitative potential and treatment needs, local justice and treatment system capabilities, and public safety concerns.

Moreover, judges and prosecutors should base their transfer decisions far more on offense history (i.e., chronicity of offending and age at which serious offending first began) than seriousness of the charged offense. Research consistently shows that offense history and age at first offending (the younger, the higher the likelihood of recidivism) are the best predictors of recidivism.

Because sentences are most effective in reducing recidivism when meted out in a graduated fashion, transfer should be used only if it is the next step in a continuum of incremental sanctions imposed on the juvenile and when previous lighter sanctions have not worked. Even in the most serious cases, rarely should transfer be imposed for a first-time offense.

Whether or not transfer has deterrent effects will likely depend on whether the juvenile or criminal justice system can implement a graduated sentence along with rehabilitative treatments that address the child (e.g., mental health problems,

school failure), family (e.g., inadequate parental supervision, poor parental discipline), and neighborhood (e.g., antisocial peer group, exposure to violence) risk factors contributing to the juvenile’s offending. Research consistently and strongly shows that the most effective rehabilitative interventions are those that are family and community based (rather than in institutional settings) and that are individually tailored to target the delinquency risk factors operating in the child’s life.

Substantial additional research is needed. Research must be conducted across states having differing transfer laws and sentencing options. Importantly, studies must measure and analyze a large number of variables relating to offense and offender characteristics as well as transfer/sentence type and use sophisticated methodologies to minimize potential selection biases. Early studies included a limited number of variables and omitted important variables that may have skewed the results.

DEVELOPMENTAL THEORIES OF CRIME

Developmental and life-course criminology (DLC) theories aim to explain within-individual changes in offending and antisocial behavior over time. In particular, they aim to explain (a) the development of offending and antisocial behavior from the womb to the tomb, (b) the influence of risk and protective factors at different ages, and (c) the effects of life events on the course of development. Whereas traditional criminological theories aim to explain between-individual differences in offending, such as why lower-class boys commit more offenses than upper-class boys, DLC theories aim to explain within-individual changes in offending over time, and especially why offending increases to a peak in the teenage years and then decreases.

This entry reviews some early criminological theories because their postulates provide the building blocks of most major DLC theories of offending. It then reviews three early DLC theories by Delbert Elliott, Gerald Patterson, and Rolf Loeber. The main part of the entry consists of a review of six major DLC theories of offending by David Hawkins and Richard Catalano, Terrie Moffitt, Robert Sampson and John Laub, David Farrington, Terry Thornberry and Marvin Krohn, and Per-Olof Wikström. It then compares and contrasts these theories and recommends how best to advance knowledge. Basically, all DLC theorists should cooperate in specifying where predictions from one theory differ from predictions from another theory and in empirically testing these different predictions.

Early Criminological Theories

The propositions of major DLC theories are based on those of earlier theories. Classic sociological theories in criminology aimed to explain between-individual differences in offending (i.e., why some people committed more offenses than other people). This was because most early criminological research was cross-sectional in nature; a sample of people (usually teenagers) were interviewed at one point in time, and correlations between influencing factors and delinquency were studied. The main aim of the early theories was to explain these correlations.

As an example, Albert Cohen suggested that lower-class boys were more criminal than other boys because they tended to fail in school and consequently felt status frustration, which encouraged them to form delinquent subcultures by whose standards they could succeed. Richard Cloward and Lloyd Ohlin proposed that delinquency was caused by the strain between what boys wanted to achieve (e.g., status, money) and what they actually could achieve; because they could not achieve their aims using legitimate means, they used illegitimate means. Travis Hirschi suggested that people committed offenses because they had weak bonding to society; he assumed that the main factor that inhibited offending was strong bonding to society. Edwin Sutherland and Donald Cressey argued that offending depended on learning antisocial norms and values, through differential association with deviant groups.

Classic psychological theories in criminology also aimed to explain between-individual differences in offending. Gordon Trasler proposed that people were inhibited from offending by the strength of the conscience; this, in turn, depended on consistent and contingent punishment of disapproved acts by parents, so that children learned to associate anxiety with disapproved behavior. Hans Eysenck agreed with this theory but proposed that children with particular personalities (those who were high on extraversion and neuroticism) were inherently poor at building conditioned responses, did not build up strong consciences, and were therefore more likely to offend.

Other theories focused on the decision to offend. Traditional deterrence theory and the later subjective expected utility theory proposed that people were trying to make rational decisions. Individuals would commit a crime if the expected benefits (e.g., based on the probability and utility of loot or peer approval) exceeded the expected costs (e.g., based on the probability and utility of parental disapproval or legal punishment). Ronald Clarke and Derek Cornish popularized a rational choice theory of offending. Other theories emphasized the role of moral inhibitions (e.g., Laurence Kohlberg's theory) or cognitive scripts (e.g., Rowell Huesmann's theory) in the decision to offend.

Many later theories incorporated ideas from earlier theories. For example, in 1985, James Q. Wilson and Richard Herrnstein suggested that

whether people choose to commit a crime in any situation depended on whether they perceive that the benefits of offending outweigh the perceived costs. They also emphasized the importance of the conscience as an internal inhibitor of offending and suggested that this was built up in a social learning process according to whether parents reinforced or punished childhood transgressions. The key individual difference factor in this theory was the extent to which people's behavior was influenced by immediate, as opposed to delayed, consequences. Wilson and Herrnstein suggested that more impulsive people were less influenced by the likelihood of future consequences and were therefore more likely to commit crimes.

In 1990, Michael Gottfredson and Hirschi proposed that offending depended on low self-control. People with low self-control were impulsive, took risks, had low cognitive and academic skills, were self-centered, had low empathy, and had short time horizons. Therefore, they found it hard to defer gratification, and their decisions to offend were insufficiently influenced by the possible future painful consequences of offending. Gottfredson and Hirschi also argued that between-individual differences in self-control were present early in life (by age 6–8 years), were remarkably stable over time, and were essentially caused by differences in parental child-rearing practices. This was the last major between-individual theory focusing on cross-sectional research.

Early DLC Theories

During the 1980s, there was a massive increase in prospective longitudinal studies of offending, in which individuals were followed from childhood into adulthood to investigate the development of antisocial behavior over time. This was because funding agencies realized that longitudinal studies were superior to cross-sectional studies in establishing causal effects because longitudinal studies could specify whether a change in a putative causal factor (e.g., parental supervision) preceded, coincided with, or followed a change in offending. In turn, longitudinal researchers formulated new DLC theories to try to explain within-individual changes over time. However, these were usually based on earlier theories.

For example, in 1985, Elliott and his colleagues combined strain, control, social learning, and differential association theories. They proposed that strain (the inability to achieve goals in socially approved ways), poor socialization (exposure to ineffective social learning and reinforcement processes), and living in a socially disorganized community caused weak bonding to conventional society. This, in turn, led to strong bonding to antisocial peer groups and ultimately to delinquency.

Patterson proposed another early DLC theory in 1982. This was a version of social learning theory that focused on ideas of coercion based on systematic observation of interactions between parents and children. The basic idea of social learning theory is simple: Actions that are rewarded are more likely to occur subsequently, and actions that are punished are less likely to occur subsequently. Patterson especially emphasized the importance of coercive actions by parents and children. If a parent behaves coercively toward a child (e.g., by shouting or threatening), the effect depends on the reaction of the child. If the child reacts coercively (e.g., by yelling or arguing) and the parent then stops being coercive, the child learns to use hostile reactions to terminate hostile situations. The main idea is that children who are raised in coercive families learn to use coercive behavior. In contrast, skillful parents use positive reinforcement (e.g., rewards) for desirable behaviors and ignore or use time-out (e.g., sending the child to his or her room) for undesirable behaviors. According to this theory, consistent and contingent reactions by parents and careful monitoring of children are effective in preventing delinquency.

Another early DLC theory was the developmental pathways theory that Loeber proposed. This suggested that there were three pathways that describe development from less serious to more serious antisocial behaviors called the *overt*, *covert*, and *authority conflict pathways*. The overt pathway describes development from minor aggression to serious violence. The covert pathway describes development from shoplifting to auto theft and burglary. The authority conflict pathway describes development from stubborn behavior to truancy. Children could progress simultaneously on all the three pathways. Another

distinctive feature of this theory is its emphasis on the timing of exposure to risk and protective factors, the varying impact that they can have at different developmental stages, and the importance of an accumulation of risk factors (noting the dose-response relationship between the number of risk factors and the likelihood of a delinquent outcome).

Six Major DLC Theories

The Elliott, Patterson, and Loeber theories were not very detailed in trying to explain within-individual changes from childhood to adulthood. The first really detailed DLC theory was proposed in 1986 by Hawkins and Catalano. Their social development model integrates social control/bonding, social learning, and differential association theories. Their key construct is bonding to society (or socializing agents), consisting of attachment and commitment. The key factor influencing offending is the balance between antisocial and prosocial bonding. The main motivation that leads to offending and antisocial behavior is the hedonistic desire to seek satisfaction and follow self-interest. This is opposed by the bond to society. Offending is essentially a rational decision in which people weigh the benefits against the costs.

There are two causal pathways, leading to antisocial or prosocial bonding. On the prosocial pathway, opportunities for prosocial interaction lead to involvement in prosocial behavior; and involvement and skills for prosocial behavior lead to rewards for prosocial behavior, which in turn lead to prosocial bonding and beliefs. On the antisocial pathway, opportunities for antisocial interaction lead to involvement in antisocial behavior; involvement and skills for antisocial behavior lead to rewards for antisocial behavior, which in turn lead to antisocial bonding and beliefs. Therefore, the antisocial pathway specifies factors encouraging offending, and the prosocial pathway specifies factors inhibiting offending. Opportunities, involvement, skills, and rewards are part of a socialization process. People learn prosocial and antisocial behavior according to socialization by families, peers, schools, and communities.

Moffitt proposed that there are two qualitatively different categories of antisocial people (differing in kind rather than in degree), namely

life-course-persistent (LCP) and adolescence-limited (AL) offenders. As indicated by these terms, the LCPs start offending at an early age and persist beyond their 20s, while the ALs have a short criminal career largely limited to their teenage years. The LCPs commit a wide range of offenses, including violence, whereas the ALs commit predominantly rebellious, nonviolent offenses such as vandalism. The main factors that encourage offending by the LCPs are cognitive deficits, an undercontrolled temperament, hyperactivity, poor parenting, disrupted families, teenage parents, poverty, and low socioeconomic status. The main factors that encourage offending by the ALs are the maturity gap (their inability to achieve adult rewards such as material goods during their teenage years) and peer influence (especially from the LCPs). Consequently, the ALs stop offending when they enter legitimate adult roles and can achieve their desires legally.

Sampson and Laub proposed a theory in which the key construct was age-graded informal social control, which means the strength of bonding to family, peers, schools, and later adult social institutions such as marriages and jobs. They primarily aimed to explain why people do not commit offenses, on the assumption that why people want to offend is unproblematic (presumably caused by hedonistic desires) and that offending is inhibited by the strength of bonding to society. The strength of bonding depends on attachments to parents, schools, friends, and siblings and also on parental socialization processes such as discipline and supervision. Sampson and Laub are concerned with the whole life course. They emphasize change over time rather than consistency and the poor ability of early childhood risk factors to predict later life outcomes. They focus on the importance of later life events (adult turning points), such as joining the military, getting a stable job, and getting married, in fostering desistance and knifing off the past from the present.

Farrington's integrated cognitive antisocial potential theory was primarily designed to explain offending by lower-class males. It integrates ideas from many other theories, including strain, control, social learning, labeling, and rational choice approaches. Its key construct is antisocial potential (AP), and it assumes that the translation from AP to antisocial behavior depends on cognitive

(thinking and decision-making) processes that take account of opportunities and victims. The theory proposes that long-term AP depends on impulsiveness, on strain, modeling, and socialization processes, and on life events, while short-term variations in AP depend on motivating and situational factors.

Following strain theory, the main energizing factors that potentially lead to high long-term AP are desires for material goods, status among intimates, excitement, and sexual satisfaction. However, these motivations only lead to high AP if antisocial methods of satisfying them are habitually chosen. Antisocial methods tend to be chosen by people who find it difficult to satisfy their needs legitimately, such as people with low income, unemployed people, and those who fail at school. Long-term AP also depends on attachment and socialization processes. AP will be low if parents consistently and contingently reward good behavior and punish bad behavior. Withdrawal of love may be a more effective method of socialization than hitting children. AP will be high if children are not attached to (prosocial) parents, for example, if parents are cold and rejecting. Disrupted families (broken homes) may impair both attachment and socialization processes. Long-term AP will also be high if people are exposed to, and influenced by, antisocial models, such as criminal parents, delinquent siblings, and delinquent peers, for example, in high crime schools and neighborhoods. Also, life events affect AP; it decreases (at least for males) after people get married or move out of high crime areas, and it increases after separation from a partner.

According to the integrated cognitive antisocial potential theory, the commission of offenses and other types of antisocial acts depends on the interaction between the individual (with his immediate level of AP) and the social environment (especially criminal opportunities and victims). Short-term AP varies within individuals according to short-term energizing factors such as being bored, angry, drunk, or frustrated or being encouraged by peers. Whether a person with a certain level of AP commits a crime in a given situation depends on cognitive processes, including considering the subjective benefits, costs, and probabilities of the different outcomes and stored behavioral repertoires or scripts. In general, people tend to make

decisions that seem rational to them, but those with low levels of AP will not commit offenses even when (on the basis of subjective expected utilities) it appears rational to do so. Equally, high short-term levels of AP (e.g., caused by anger or drunkenness) may induce people to commit offenses when it is not rational for them to do so.

Thornberry and Krohn proposed an interactional theory that particularly focused on factors encouraging antisocial behavior at different ages. At the earliest ages (birth to 6 years), the three most important factors were neuropsychological deficit and difficult temperament (e.g., impulsiveness, negative emotionality, fearlessness, poor emotion regulation), parenting deficits (e.g., poor monitoring, low affective ties, inconsistent discipline, physical punishment), and structural adversity (e.g., poverty, unemployment, welfare dependency, a disorganized neighborhood). At ages 6–12 years, neighborhood and family factors were particularly salient. At ages 12–18 years, school and peer factors dominated. Thornberry and Krohn also suggested that deviant opportunities, gangs, and deviant social networks were important for onset at ages 12–18 years. They proposed that late starters (ages 18–25 years) had cognitive deficits, such as low intelligence and poor school performance, but that they were protected from antisocial behavior at earlier ages by a supportive family and school environment. At ages 18–25 years, they found it hard to make a successful transition to adult roles, such as employment and marriage. Thornberry and Krohn also suggested that there was reciprocal causation; the child's antisocial behavior elicited coercive responses from parents, school disengagement, and rejection by peers and made antisocial behavior more likely in the future.

Wikström proposed a situational action theory that aimed to explain moral rule breaking. The key construct underlying offending is individual criminal propensity, which depends on moral judgment and self-control. In turn, moral values influence moral judgment, and executive functions influence self-control. Wikström suggests that temptations and provocations in situations are the main motivators. Opportunities cause temptation, friction produces provocation, and monitoring or the risk of sanctions has a deterrent effect. Learning processes are included in the theory since it is

suggested that moral values are taught by instruction and observation in a socialization process and that nurturing (the promotion of cognitive skills) influences executive functions.

Comparing and Contrasting Six Major DLC Theories

The six major DLC theories differ in many important respects. In a 2006 publication, Farrington compared and contrasted most of these DLC theories in regard to their predictions about 30 key topics. For example, some theories, such as Sampson and Laub's, mainly focus on why people do not offend. Others, such as Thornberry and Krohn's, mainly focus on why people do offend. Still others, such as Hawkins and Catalano's, include both factors encouraging offending and factors inhibiting offending. Some theories postulate an underlying theoretical construct (e.g., AP in Farrington's theory), while others (e.g., Moffitt's theory) focus only on antisocial behavior. Some theories (e.g., Moffitt) suggest that there are distinct types of offenders, while others (e.g., Sampson and Laub) assume that offending varies on a continuum. Some theories (e.g., Moffitt) focus more on childhood development and the onset of offending, whereas others (e.g., Sampson and Laub) focus more on adult development and on desistance from crime. Some theories (e.g., Farrington) try to explain the commission of crimes, but others (e.g., Thornberry and Krohn) focus only on the development of offenders. Finally, some theories (e.g., Moffitt) focus mainly on psychological factors, whereas others (e.g., Sampson and Laub) focus more on the social environment.

All of these theories are plausible and explain key findings on the development of offending. However, it is extremely difficult to decide which theory is the best or even whether one theory is better than another. This is because, in most cases, the theories have been empirically tested only by the theorists who proposed them. More independent tests of theories are needed. More efforts should be made to compare and contrast the different theories in regard to their predictions and explanations of empirical results. In a 2005 publication, Farrington challenged DLC theorists to specify how their theories addressed 13 key empirical questions and 11 key theoretical

questions. However, few of the theorists took up this challenge. It would be highly desirable to systematically compare how each DLC theory answers all these questions. It would also be highly desirable to specify crucial tests, where predictions from one DLC theory clearly differ from predictions from another DLC theory. Ideally, all DLC theorists should cooperate in specifying and testing their theories, in the interest of developing better theories that explain and predict more empirical findings on within-individual changes in offending through life.

DEVELOPMENTAL THEORIES OF CRIME: MALTREATMENT

Child maltreatment is a serious public health concern affecting millions of children each year in the United States and abroad. Several major prospective longitudinal studies have followed abused and

neglected children from childhood into adolescence or adulthood and have found that these children are at increased risk of delinquency, crime, and violence. Many theories have been offered to explain how these childhood maltreatment experiences lead to the development of criminal behavior and, in particular, violent criminal behavior. One of the common assumptions is based on notion of a *cycle of violence*, whereby experiencing violence in childhood is thought to lead to the perpetration of violence in adolescence and adulthood. This entry reviews social learning, strain, attachment, social information processing theories, as well as maladaptive coping, possible changes in physiological functioning, behavioral genetic and ecologic theories that have been offered to explain how childhood maltreatment affects the development of later violent and criminal behavior.

Social Learning Theory

Social learning is perhaps the most popular theory that has been used to explain the cycle of violence. As part of his theory, Albert Bandura proposed that children acquire behaviors through modeling and reinforcement contingencies in the context of social interactions. Children learn behaviors by imitating other people's behavior, and observing the behavior of a parent or someone else of high status is thought to provide a particularly influential model. For example, physical aggression within a family provides a powerful model for children to learn aggressive behaviors and to learn that these behaviors are appropriate ways to resolve conflicts. Some research has found that children who experience spanking (a form of corporal punishment that is not necessarily abusive) were more likely to perceive aggression as an effective strategy for resolving interpersonal conflicts. Based on social learning theory, one would expect that criminal outcomes would reflect the type of victimization experienced and that victims of physical abuse would become physically violent. However, the picture appears to be more complex. Consistent with social learning theory, two longitudinal studies found that physical abuse (i.e., being the victim of violence as a child) was associated with a high risk of subsequent arrests for violence. Other studies have found that

physical abuse predicted youth violence perpetration. However, not predicted by social learning theory, two of the prospective studies revealed that neglected children also had increased rates of arrests for violence compared to nonabused and nonneglected children, and the degree of increased risk was very similar to that of the physically abused children. These findings call attention to the fact that childhood neglect may also lead to violent behavior and suggest that behavioral modeling alone is not an adequate explanation for the cycle of violence.

Attachment Theory

Attachment theory, originally developed by John Bowlby and Mary Ainsworth, has played an important role in attempts to understand the development of violent behavior in children who grow up in abusive childhoods. Attachment refers to the early bond that an infant develops with a caretaker and is the basis for an *internal working model* of the world that functions as a framework for subsequent interactions with the interpersonal environment, including other caretakers, school, peers, romantic partners, and the community at large. According to attachment theory, abuse, inconsistency, or rejection from a primary caretaker disrupts a child's bonds and feelings of security and leads children to develop a hostile view of the world and other people. Children from abusive backgrounds, thus, tend to perceive ambiguous interactions with others as hostile and to respond aggressively. It is thought that this pattern can develop into violent behavior in adulthood.

Social Control Theory

Another theory also emphasizes the impact of family bonds (or the lack of bonds) on a child's behavior. Travis Hirschi's social control theory proposes that people will avoid delinquent and criminal behavior when they are bonded to the society. This means that children who are attached to parents, peers, schools, and conventional beliefs will be less likely to engage in delinquent and criminal behavior. Because of the focus on bonding and relationships with parents and other significant adults, social control theory is relevant to understanding how child abuse and neglect may

lead to an increase in risk of crime and violence. As noted in the earlier section on attachment theory, there has been extensive attention to the ways in which child maltreatment disrupts attachments to create an insecure child. Social control theory would suggest that child maltreatment disrupts the social bonds necessary for prosocial behavior and, thus, increases risk of crime and violence.

General Strain Theory

In his strain theory, Robert Agnew has argued that, in addition to failure to achieve economic or other goals, delinquency and crime are caused by the inability to escape painful or aversive situations such as child abuse and neglect. In his attention to the role of child abuse and neglect, he pointed explicitly to the strain associated with the impact of verbal and physical abuse. If a person's focus or goal is for monetary success or higher levels of social class, then abused and neglected children would have barriers to achieving these goals because of limited educational and occupational success—a negative outcome that has been documented in some groups of maltreated children. Agnew has also suggested that juveniles who experience abuse may engage in delinquent behaviors to escape from or reduce the aversive conditions by running away from home. Other examples of attempts to escape painful events, stressful life conditions, or frustrations may lead to criminal coping. The individual may lack the skills and resources to cope in a legitimate (legal) manner and may try to make money through illegal means. Coping with parental rejection (as in neglect) may lead to weak bonds with parents and poor supervision leading to increased risk of delinquent and criminal behavior. These strains may also lead to violence through the person's striking out against others in anger.

Social Information Processing Theory

Other researchers have extended the idea of a hostile view of the world and speculated that physical abuse affects social processing ability, and this deficiency is related to aggression. Similar to attachment theory, this approach proposes that abused children tend to perceive hostile intent in ambiguous and harmless interactions. Specifically,

Kenneth A. Dodge, John E. Bates, and Gregory S. Pettit have suggested that severe physical harm during early childhood leads to chronic aggression by bringing about the development of biased and deficient social information processing patterns. The theory postulates that such children are less likely to respond to social cues, more likely to react toward others with hostility, and fail to deal with personal problems in a competent fashion. These researchers found that 4-year-old children whose mothers reported having used physically harmful discipline showed deviant patterns of processing social information at age 5, and these were, in turn, associated with aggressive behavior.

Maladaptive Coping

Another theory is that physically abused children may adopt certain styles of coping that may be maladaptive. For example, characteristics such as a lack of realistic long-term goals, being conning or manipulative, pathological lying, or glibness or superficial charm might begin in the child as a means of coping with an abusive home environment. Adaptations or coping styles that may be functional at one point in development (e.g., running away, avoiding an abusive parent, alcohol or drugs, or desensitizing oneself against feelings) may later compromise the person's ability to draw upon and respond to the environment in an adaptive and flexible way.

Neurophysiological Models

A very different approach to understanding the development of maltreated children focuses on how the experiences of childhood abuse and neglect may lead to bodily changes that, in turn, relate to the development of antisocial and aggressive behaviors. For example, as a result of being beaten continually or as a result of the severe stress associated with intermittent physical abuse, a child might become *desensitized* to future painful or anxiety-provoking experiences. Thus, this desensitization might influence the child's later behavior, making him or her less emotionally and physiologically responsive to the needs of others, callous and non-empathic, and without remorse or guilt. Relatedly, physical abuse may lead to

stress, which, if occurring during critical periods in development, may give rise to abnormal brain chemistry that may lead to aggressive or withdrawn behaviors at later points in life.

Michael DeBellis has theorized that repetitive activation of physiological stress response processes can have a global and adverse impact on neurological development, impeding capacities related to stress response and coping, managing emotional arousal, planning, and decision-making. Chronic exposure to stress, such as in child abuse or neglect, may result in an elevated stress response, which is thought to prime individuals to act aggressively in stressful situations, or to a diminished response associated with desensitization to stress.

Some research with animal models has supported these neurobiological processes involved in the cycle of violence. However, the extent to which one can generalize from the animal research to humans is questionable, although the similarities between the concepts operationalized in the non-human models (stress, anxiety, and rearing conditions of maltreatment) and in the child development literature invite serious consideration.

Behavioral Genetics

The theories described thus far presume that the relationship between childhood abuse and neglect and delinquent, criminal, or violent behavior is due to the direct effects of being exposed to a violent childhood environment. It is also possible that there are genetic predispositions to certain forms of behavior that are passed on from generation to generation.

Sara Jaffee has written about a variety of behavioral genetic theories that have been developed to explain the intergenerational transmission of violence. The first and simplest theory suggests that the intergenerational cycle of violence is explained, at least in part, by transfer of inherited traits from parents to offspring. In other words, family resemblance in violent behaviors is due to shared genetics rather than the environmental effects of violence. Violent parents are more likely to abuse their children and also to transmit increased genetic risk of violent behavior. Thus, maltreatment could be a marker of genetic risk of violence (i.e., having antisocial parents) rather than the cause of violence. A

second possibility is that certain genotypes in children could bring about abuse from parents, although the results of twin studies (either with children or parents) have not supported this idea. A third possibility is that maltreatment leads to epigenetic changes that predispose individuals to antisocial or violent behavior.

Tania Roth and Frances Champagne described evidence suggesting that changes in the activity of genes, established through epigenetic mechanisms (i.e., changes that modify the activation of certain genes but not the genetic code sequence of DNA), may be a consequence of early- and later-life adversity. They draw upon results from animal models of neglect, abuse, chronic stress, and trauma and suggest that adversity has a lasting epigenetic impact. Furthermore, they suggest that this impact may not be limited to those individuals who have been directly exposed to adversity but may also be evident in subsequent generations; thus, there may be an *inheritance* of stress susceptibility that may involve epigenetic rather than genetic variation.

Ecological Theory

Finally, most theories of the effects of child maltreatment focus on risk of delinquent, criminal, or violent criminal behavior from an individual or family perspective. However, other scholars argue that child maltreatment takes place in a social as well as a family context, and as such, there is a need to understand the contributions of the ecological systems in which these children live (family, school, peers, and neighborhoods). This theory hypothesizes that criminal behaviors do not occur in isolation but rather develop out of interactions among these factors in the broader social context, including the presence of criminogenic opportunities, such as guns, gangs, and drugs. Neighborhood conditions might also buffer or reduce the relationship between child maltreatment and offending.

DIAGNOSTIC AND STATISTICAL MANUAL OF MENTAL DISORDERS, CLASSIFICATION OF PSYCHOPATHY IN

The *Diagnostic and Statistical Manual of Mental Disorders* (DSM), published by the American Psychiatric Association, is the reference book widely used by physicians and mental health professionals for the diagnosis of mental disorders,

and it is consistent with the International Classification of Disease coding system. Psychopathy or psychopathic personality is not a listed diagnosis. The DSM is used in a variety of settings, including forensic (related to the legal system), clinical, research, and social purposes. This entry describes psychopathy and explains where it fits in the evolving DSM classification system.

Psychopathy is a construct without consensual definition. Historically, Hervey Cleckley, since the 1940s, and Robert D. Hare, since the 1980s, have had the most impact on the understanding of psychopathy. Cleckley's classic, *The Mask of Sanity*, listed 21 features in 1941; this was narrowed to 16 in 1976. Subsequently, Hare developed the Psychopathy Checklist (PCL) in 1985, a revised version in 1991 (PCL-R), and the current version (PCL-R) in 2003 to measure psychopathy based on Cleckley's work. This 20-item inventory generates two to four factors (clusters of items that share a significant similarity), namely, interpersonal, affective, lifestyle, and antisocial, that reflect aspects of psychopathy, the unifying superordinate factor. The two-factor model more clearly distinguishes psychopathy, psychopathic personality traits (Factor 1, e.g., pathological lying, manipulative, superficial charm, grandiose sense of self-worth, lack of empathy) from antisocial personality disorder (ASPD), antisocial behavior (Factor 2, e.g., impulsivity, parasitic lifestyle, irresponsible, juvenile delinquency, revocation of conditional release), suggesting differences.

The PCL-R correlates with DSM ASPD, narcissistic personality disorder, and borderline personality disorder, indicating psychopathic features in each. High PCL-R scorers are prototypically male social predators with little insight, for whom there is no effective treatment and who often end up in correctional settings. Although the PCL-R is a standard instrument for assessing criminality and recidivism risk, it has its critics.

Other characterizations of psychopathy have emerged in the 21st century. These include a triarchic (disinhibition, meanness, and boldness) depiction, a fearless-dominance and impulsive-antisociality perspective, and evaluations of psychopathy in terms of three- and five-factor models of personality (e.g., low agreeableness, low conscientiousness, and a mixture of high and low neuroticism facets). In addition, the dark (malevolent)

triad consists of three overlapping traits, namely, psychopathy (including antisocial behavior), narcissism, and Machiavellianism. The dark tetrad adds everyday sadism to that list.

The term *personality disorder (PD)* is used differently in various editions of the *DSM*, and features of psychopathic personality are evident without using that label. The first edition of the *DSM*, *DSM-I*, was published in 1952 to provide a unified contemporary classification system and standard nomenclature for clinical diagnosis and insurance reimbursement. *DSM-I* described individuals with PD as having lifelong defective personalities that did not cause personal distress. According to the *DSM-5* (2013) description, however, PD causes personal distress or functional impairment and represents significant deviation from one's culture. In addition, a disordered personality is rigid, pervasive, stable, and evident by adolescence or young adulthood.

In *DSM-I*, a pre-*DSM* term, psychopathic personality with emotional instability, was reclassified as emotionally unstable personality. Constitutional psychopathic state and psychopathic personality were renamed *sociopathic personality disturbance*, antisocial reaction. Pseudosocial personality and psychopathic personality with asocial and amoral trends were updated to sociopathic personality disturbance dissocial reaction, all under the heading Personality Trait Disturbance (capitalization provided by *DSM-I*). Reaction meant environmentally caused rather than organic (biological) etiology.

DSM-II (1968) provided prototypic descriptions of disorders. This minimized restraint on clinical judgment but produced unreliable (low agreement among clinicians) diagnoses. *DSM-II* used a single diagnosis, antisocial personality, to refer to unsocialized individuals who blamed others and were callous, frequently conflicting with society, selfish, incapable of feeling guilt, and undeterred by punishment.

The *DSM-III* (1980) major revamp provided behavior-based criteria, more specificity and reliability, and solidified ASPD as the chosen label. ASPD required evidence of conduct disorder before age of 15 years, plus behaviors indicating social norms' violations, such as criminality, child maltreatment, conning others, and reckless disregard for personal safety. ASPD omitted some

psychopathic descriptors, such as superficial charm and lack of remorse. These might be inferred but were not listed criteria. In addition, ASPD overrepresented criminogenic features, thereby limiting noncriminal applications. *DSM-III-R* (1987) added two criteria (assessed by behaviors): lacks remorse and is impulsive. Only four of 10 criteria were required for ASPD diagnosis.

Although controversial, to minimize diagnostic overlap, psychopathic features were deliberately placed in either *DSM-IV* (1994) narcissistic personality disorder or ASPD, not both. The *DSM-IV-TR* (2000) lists ASPD, sociopathy, psychopathy, and dissocial PD as synonyms, but ASPD is the identified diagnosis. The *DSM-5* continued the predominant focus on antisocial aspects of psychopathy and used the label ASPD. Descriptive criteria favor applications to criminal settings.

Understanding psychopathy changes as research guides scientifically based professional thinking. Although not officially acknowledged, Cleckley and Hare's influence is evident across *DSM* ASPD versions, while triarchic disinhibition and meanness (but not boldness) are reflected in *DSM-5* ASPD. Conjecture remains whether adaptive traits of the so-called successful, noncriminal psychopaths will be included in future *DSM* editions and whether psychopathy will be a recognized ASPD specifier.

DIFFERENTIAL ASSOCIATION THEORY

Edwin Sutherland's *differential association theory* marked a watershed in criminology. The theory, which argues that criminal behavior, like any behavior, is learned in interaction within social groups, dominated the discipline for decades and brought sociology to the forefront of criminology. This entry reviews Sutherland's theory of differential association, discusses attempts at revision, and assesses the empirical status of the theory.

The Theory of Differential Association

In 1947, Sutherland stated differential association theory as a set of nine propositions, which introduced three concepts—normative conflict, differential association, and differential group organization—that explain crime at the levels of the society, the individual, and the group.

Normative Conflict: The Root Cause of Crime in Society

At the societal level, crime is rooted in normative conflict. For Sutherland, primitive, undifferentiated societies are characterized by harmony, solidarity, and consensus over basic values and beliefs. Such societies have little conflict over appropriate behaviors and, consequently, little crime. With the industrial revolution, however, modern societies developed advanced divisions of labor, market economies, and a breakdown in

consensus. Modern industrial societies become segmented into groups that conflict over interests, values, and behavior patterns. Consequently, they are characterized by specialization rather than similarity, coercion rather than harmony, and conflict rather than consensus. They tend to have high rates of crime. Sutherland hypothesized that high crime rates are associated with normative conflict, which he defined as a society segmented into groups that conflict over the appropriateness of the law: Some groups define the law as a set of rules to be followed under all circumstances, while others define the law as a set of rules to be violated under certain circumstances. Therefore, when normative conflict is absent in a society, crime rates will be low; when normative conflict is high, societal crime rates will be high. In this way, crime is ultimately rooted in normative conflict.

Differential Association Process: Explanation of Individual Criminal Acts

At the individual level, the process of differential association provides a social psychological explanation of how normative conflict in society translates into individual criminal acts. Accordingly, criminal behavior is learned in a process of communication in intimate groups. The content of learning includes two important elements. First are the requisite skills and techniques for committing crime, which can range from complicated, specialized skills of computer fraud, insider trading, and confidence games to the simple, readily available skills of assault, purse snatching, and drunk driving. Such techniques are necessary but insufficient to produce crime. Second are definitions favorable and unfavorable to crime, which consist of motives, verbalizations, or rationalizations that make crime justified or unjustified and include techniques of neutralization. For example, definitions favorable to income tax fraud include "Everyone cheats on their taxes" and "The government has no right to tax its citizens." Definitions favorable to drunk driving include "I can drive fine after a few beers" and "I only have a couple of miles to drive home." Definitions favorable to violence include "If your manhood is threatened, you have to fight back" and "To maintain respect, you can never back down from a fight."

Definitions favorable to crime help organize and justify a criminal line of action in a particular situation. They are offset by definitions unfavorable to crime, such as “Tax fraud deprives Americans of important programs that benefit the commonwealth,” “All fraud and theft is immoral,” “If insulted, turn the other cheek,” “Friends don’t let friends drink and drive,” and “Any violation of the law is wrong.” These examples illustrate several points about definitions of crime. First, some definitions pertain to specific offenses only (e.g., “Friends don’t let friends drink and drive”), whereas others refer to a class of offenses (e.g., “All fraud and theft is immoral”), and still others refer to virtually all law violation (e.g., “Any violation of the law is wrong”). Second, each definition serves to justify or motivate either committing criminal acts or refraining from criminal acts. Third, these definitions are not merely *ex post facto* rationalizations of crime but rather operate to cause criminal behavior.

Sutherland recognized that definitions favorable to crime can be offset by definitions unfavorable to crime. He therefore hypothesized that criminal behavior is determined by the ratio of definitions favorable to crime versus unfavorable to crime. Furthermore, he recognized that definitions are not all equal. Definitions that are presented more frequently, for a longer duration, earlier in one’s life, and in more intense relationships receive more weight in the process producing crime.

The individual-level hypothesis of differential association theory is that a person will engage in criminal behavior if the following three conditions are met:

1. The person has learned the requisite skills and techniques for committing crime.
2. The person has learned an excess of definitions favorable to crime over unfavorable to crime.
3. The person has the objective opportunity to carry out the crime.

According to Sutherland, if all three conditions are present and crime does not occur, or a crime occurs in the absence of all three conditions, the theory would be wrong and in need of revision. Thus, in principle, the theory is falsifiable.

The process of differential association with definitions favorable and unfavorable to crime is structured by the broader social organization in which individuals are embedded. This includes the structures and organization of families, neighborhoods, schools, and labor markets. This organization is captured by the concept of differential social organization.

Differential Social Organization: Explanation of Group Rates of Crime

At the group level, differential social organization provides an organizational explanation of how normative conflict in society translates into specific group rates of crime. According to *differential social organization*, the crime rate of a group is determined by the extent to which that group is organized against crime versus organized in favor of crime. In industrialized societies, the two forms of organization exist side by side. Indeed, these two forms are sometimes interwoven in complex ways, such as when police take bribes and participate in organized extortion or baseball players take steroids in full view of teammates. Sutherland hypothesized that the relative strength of organization in favor of crime versus against crime could explain the crime rate of any group or society. Thus, compared to suburban neighborhoods, inner-city neighborhoods are weakly organized against street crimes and strongly organized in favor of such crimes. Compared to other groups, the Mafia is strongly organized in favor of crime and weakly organized against crime. Compared to the United States, Japan is strongly organized against crime and weakly organized in favor of crime. Ross Matsueda extended differential social organization theory to crime as collective behavior, arguing that definitions of crime become collective action frames, which operate to mobilize individuals for or against collective acts of crime.

The group-level process of differential social organization is linked to the individual-level process of differential association. Groups that are strongly organized in favor of crime display numerous and intense definitions favorable to crime. Conversely, groups that are strongly organized against crime display numerous and intense definitions unfavorable to crime. It follows that

differential social organization explains group crime rates by influencing the availability of definitions favorable and unfavorable to crime within the group. When groups are strongly organized in favor of crime and weakly organized against crime, they will present an abundance of definitions favorable to crime and few definitions unfavorable to crime. Individuals in such groups have a high probability of learning an excess of definitions of crime. Whether they do depends on their actual learning. Even in high crime communities, some residents are isolated from the abundant criminal definitions and exposed to the few anti-criminal definitions in the community. Those residents will refrain from crime because of an excess of definitions unfavorable to crime. The opposite also holds. In low-crime communities, some residents are exposed to the few criminal definitions in the community and isolated from the abundant anti-criminal definitions. Given the opportunity and skills, they will engage in crime because of an excess of definitions favorable to crime.

Extensions and Empirical Tests of Differential Association

Since it was presented in its final form in 1947, the theory has stimulated substantial scholarly attention. This includes attempts to revise or modify the theory to specify the learning principles and incorporate the process of taking the role of the other from symbolic interactionism as well as conduct empirical tests on the theory's key propositions.

Extensions of Differential Association Theory

Although the core features of differential association theory have persisted to the present, the theory has undergone several modifications and extensions. Early attempts to modify the theory specified hypotheses of *differential identification*, in which individuals identify with either criminals or noncriminals, and *differential anticipation*, in which individuals anticipate the consequences of delinquent or nondelinquent behavior.

Perhaps the most elaborate revision is associated with Ronald Akers, who in 1998 incorporated social learning principles into the theory, which posits that crime is initially learned through direct

imitation or modeling. The probability of continuing criminal behavior is determined by *differential reinforcement*, the relative rewards and punishments following the act. Reinforcement can be direct or vicarious, whereby simply observing another's criminal behavior being reinforced will reinforce one's own criminal behavior. Definitions of crime are learned through this process and affect behavior directly as well as indirectly by serving as cues (discriminative stimuli) for law violation.

A more recent extension of differential association theory incorporates the symbolic interactionist concept of taking the role of the other as a link between group control, cognition, and behavior. Here, taking the role of significant others and considering delinquency from the standpoint of others is a cognitive process by which anticipated reactions of others, reflected appraisals of self from the standpoint of others (the looking glass self), and delinquent peer associations (along with habits) lead to future delinquency. Such processes produce group social control of both delinquent and nondelinquent acts, and therefore, delinquency is a result of *differential social control*, the relative strength of conventional versus delinquent group controls. Differential social control specifies specific mechanisms by which groups control members' behavior, while retaining Sutherland's emphasis on the learning of delinquency and the importance of definitions of law violation.

Empirical Tests of Differential Association Theory

Empirical studies of differential association generally use self-report surveys of adolescents and young adults. A key issue is how to measure an excess of definitions favorable to crime, a prerequisite for testing the theory. Long ago, Matsueda argued that if definitions of law violation can be viewed as a single continuum, they can be treated as a latent variable with operational implications for fallible survey measures of definitions. This strategy found that definitions of delinquency mediated effects of parent and peer attachment on delinquent behavior, and therefore, differential association is supported over social control theories for Black and non-Black

youth. Panel studies have also supported the hypothesis that definitions are causally linked to delinquency and violence for males and females and that techniques for monetary crimes are important.

Empirical research has also found some support for the hypothesis that differential reinforcement adds explanatory power in models of delinquency. The concepts of imitation and anticipated social rewards from crime appear to add to the explanation of delinquency. Finally, research beginning in the late 1990s suggested that delinquent peer association has a smaller effect on delinquency when estimated longitudinally and disentangling peer selection from peer effects and when measuring delinquent peers from the peers themselves. Differential association has been linked to social network theory and found that network density and centrality of delinquent peer groups are key predictors of delinquency. In sum, most empirical research finds general support for differential association and social learning theories.

Future Directions

Differential association theory remains an important theoretical perspective in criminology, continuing to stimulate empirical research and attempts at revision. Although historically most research has focused on the individual differential association process, beginning in 2006, there has been a resurgence of interest in the sociological counterpart, differential social organization. The latter has opened new puzzles and provided a framework for incorporating sociological mechanisms governing social structure and social organization.

DOMESTIC VIOLENCE COURTS

Since the 1990s, a variety of legal responses to domestic violence have been adopted, including mandatory arrest policies and specialized prosecution units. Simultaneously, victim advocates have developed shelters and supportive programs for victims and children, and worked with other partners to create community interventions with the dual goals of protecting victims and decreasing abuse by perpetrators of domestic violence, such as batterer intervention programs.

Specialized domestic violence courts were informed by such reforms in the legal and advocacy communities as well as a broader problem-solving court movement, such as drug, mental health, community, and reentry courts. Although each problem-solving model has distinct goals and elements, some propose that these models are unified by an overarching shift in focus from the legal process exclusively to more substantive outcomes, such as reduced recidivism, enhanced victim services, and greater responsiveness to community needs. In fact, a 2009 national survey of domestic

violence courts and victim advocates detected broad agreement concerning the overarching goals of domestic violence courts as victim safety and offender accountability. Since the earliest dedicated domestic violence courts opened in the mid-1990s, more than 200 dedicated courts have been established to address *criminal* domestic violence cases across the United States. The same 2009 national survey identified domestic violence courts in 27 states across the country as well as internationally (there were more than 50 in Canada and nearly 100 in England by 2008). In addition, *integrated* or *one family/one judge* courts as well as courts addressing *civil cases* have been developed across the country.

This entry provides an overview of the various models of domestic violence courts and reviews the underlying principles behind a dedicated domestic violence court.

Types and Models

In a *criminal domestic violence court*, criminal cases are heard on a separate calendar by one or more dedicated judges. Eligible charges vary by jurisdiction and may include misdemeanor- or felony-level offenses (or both). While some jurisdictions have specific penal code designating *domestic violence* charges, other common criminal charges may include assault, harassment, menacing, stalking, and criminal violation of a protective (restraining) order. Likewise, precise definitions of eligible relationships between parties vary by jurisdiction, with many courts requiring an intimate partner relationship (typically including parties that are or have been married or living together or that have children in common; in some jurisdictions, a dating relationship is sufficient).

A *dedicated civil protective order docket* utilizes a separate calendar whereby one or more specially trained judges hear all requests for civil protective (restraining) orders. Some civil protective order dockets also enforce the orders handed down by the court; others do not. Violations of civil protective orders may be heard in either civil or criminal court; some civil protective order dockets are able to handle both civil and criminal actions, whereas others hear only future civil proceedings.

The underlying idea behind *integrated domestic violence courts* is to bring before a single judge *all* of a family's interrelated cases in which the underlying issue is domestic violence. Under this model, criminal domestic violence charges as well as civil protective orders and, in some jurisdictions, related civil cases such as child custody and visitation, abuse and neglect, and divorce actions are calendared before a single judge who can address interrelated family problems in a comprehensive manner.

Key Components

Unlike drug courts, domestic violence courts do not have a national trade organization or a nationally recognized set of core components. However, such courts are generally designed to promote victim safety and defendant accountability, informed judicial decision-making, consistent handling of all criminal domestic violence matters, efficient case processing, procedural fairness, and a concentration of social services for victims and their children. These specialized courts can also build upon other legal responses to domestic violence, including mandatory arrest, a dedicated domestic violence unit within the prosecutor's office, and evidence-based prosecution (a method in which prosecutors rely on material evidence to prosecute a case rather than the cooperation of the victim). Toward these ends, domestic violence courts commonly implement the following components.

Dedicated Court or Docket for All Domestic Violence Cases

One or more dedicated judges preside over all domestic violence matters (either criminal or civil, or both). A specially trained judge can tailor his or her orders to address all issues, including—as appropriate—criminal and civil protective orders for victims; bail conditions, sentences, treatment mandates, and sanctions for reoffending perpetrators; and visitation and custody orders, support, divorce, and services and treatment services for children. A dedicated judge promotes consistency in handling domestic violence matters and, particularly in integrated models, enables the judge to access comprehensive case information.

Key to the dedicated domestic violence court model is courthouse safety considerations. Domestic violence courts typically create protocols to enhance courthouse safety, including additional court officers who monitor court grounds and parking lots, separate waiting areas for victims and their children, and staggered arrival and departure times for litigants.

Comprehensive Resources for Families

Domestic violence courts seek to provide services to both victims and perpetrators. In criminal domestic violence courts, referrals are often available to each person affected by the crimes. Through a resource coordinator or other specialized staff member, adult and child victims are connected to supportive services, while perpetrators are often mandated to a batterer's program. Courts may also refer perpetrators to substance abuse programs, parenting classes, mental health services, or other treatment for issues co-occurring with the intimate partner violence. Family and integrated models enable the court to treat the entire family, referring adult and child victims to supportive services while holding the offender accountable through mandated programs. In addition, civil and integrated courts work closely with supervised visitation centers to ensure swift referral where necessary. Civil and integrated courts also seek to enhance litigant access to civil legal service, often having attorneys for both parties on-site for immediate referral.

Domestic violence courts seek to be culturally responsive to the needs of litigants, creating protocols and identifying resources that reflect the language and cultural needs of victims and perpetrators, such as specialized domestic violence tribal courts, innovative collaborations with deaf services, and training of court interpreters on domestic violence.

Compliance Monitoring

Typically, domestic violence courts hold regular compliance review calendars. Increased communication and coordination between the court, service providers, and probation is key to improving accountability for perpetrators. Some courts

employ resource coordinators to facilitate this communication; representatives from accountability programs can also appear at court to communicate directly with the judge about the perpetrators' compliance with mandated programs. With representatives from probation, the defense bar, the prosecutor's office, and batterer's programs present, the judge can make swift and consistent decisions if a perpetrator fails to comply with court orders. Judges in integrated and civil courts can also monitor compliance with civil protective order conditions, child support payments, supervised visitation referrals, and parenting-time plans. Responses to noncompliance may include more frequent court appearances, modified protective (restraining) orders, visitation or support, amending or revoking probation, or jail time. The resource coordinator is able to refer offenders to a multitude of programs, including substance abuse treatment, parenting classes, and batterers' programs.

Advocacy for Victims

Increased victim safety is a central goal of domestic violence courts. With that in mind, specialized courts work closely with community victim service providers and commonly have a dedicated victim advocate present during court sessions to provide domestic violence victims with safety planning, counseling, and access to services. Advocates communicate with the resource coordinator to ensure that victims and their children receive coordinated services. The victim advocate also ensures that victims know the status of their cases and is available to escort victims to meetings with the district attorney or other social service agencies. Domestic violence courts seek to coordinate advocacy services for victims to ensure that victims have access to both community-based and system-based advocates (e.g., through the prosecutor's office).

Specialized Training

Judges presiding in domestic violence courts receive special training, which covers not only operational and legal matters but also the dynamics of domestic violence and the impact of domestic violence on children. Court personnel, such as

clerks and court security, also receive specialized training, ensuring that all individuals staffing the court are sensitive to the unique dynamics surrounding domestic violence.

Community Partner Involvement

Domestic violence courts work closely with a network of stakeholders, including police, probation, prosecutors, defense counsel, civil attorneys, victim service agencies, batterers' programs, mental health services, substance abuse treatment providers, and children's services and lawyers for children. It is critical that the courts provide continuing forums for communication through regular meetings after implementation. These stakeholder meetings are an important avenue for information sharing and checking in; the meetings can also be a venue for ongoing education.

Data Collection

The active collection and analysis of data—measuring outcomes and process, costs, and benefits—are crucial tools for evaluating the effectiveness of operations and encouraging continuous improvement. Public dissemination of this information can be a valuable symbol of public accountability.

Research on Domestic Violence Courts

Research on the impact of domestic violence courts has been mixed. Criminal domestic violence courts have been most widely studied, with outcome evaluations examining criminal justice outcomes such as recidivism, case processing, dispositions, and sentences. Overall, rigorous quasi-experimental studies have found mixed results in terms of court impacts on recidivism. The impact of domestic violence courts on sentencing practice is similarly unclear. Various domestic violence courts have been associated with both a greater and a lesser use of jail sentences than traditional courts. Regarding conviction rates, although the results are far from unambiguous, multiple studies have linked the implementation of specialized domestic violence courts to increased conviction rates. In contrast, there is evidence that domestic violence courts

are more likely than nonspecialized courts to mandate offenders to a wide range of special conditions; domestic violence courts are also more likely to connect victims to services than nonspecialized courts. Results with regard to case processing efficiency have also been more conclusive, with several rigorous studies finding that criminal domestic violence courts speed case processing.

A series of evaluations of the New York state integrated domestic violence model also found that, due to same-day scheduling of cases, integrated courts reduced the number of trips that litigants were required to make to courts, though individual cases generally take longer to reach resolution in the specialized courts. Integrated courts further appeared to detect more violations of protective orders and result in more mutually favorable outcomes in family court cases. As compared to criminal domestic violence courts, one site was found to result in more criminal convictions as well as more severe convictions. This finding was primarily attributed to the increased victim participation in integrated courts, where victims often have ongoing civil cases. Other New York findings were mixed. Findings from an evaluation of an integrated court in Vermont suggested decreases in both case processing time and reconviction; however, methodological issues mean that these findings should be interpreted with extreme caution. In general, research on integrated models suffers from methodological weaknesses; additional research on integrated models is called for.

Research on litigant and stakeholder experiences in domestic violence courts is generally positive.

Final Thoughts

Since the late 1990s, domestic violence courts have been making great strides to better reach their goals of enhancing victim safety and offender accountability. More recently, these courts have been looking at the large body of research on what works to reduce recidivism with the general criminal population and applying those evidence-based best practices into their court policies and procedures. Specifically, courts are using domestic violence risk assessments to inform decisions regarding

compliance, supervision, protective order conditions, and parenting-time plans. Many are also focusing on improving compliance through enhanced procedural justice. While more research is needed to identify how these practices specifically impact outcomes in domestic violence cases, it is clear that domestic violence courts can learn from the growing body of research and strengthen their policies to better serve victims and offenders.

DOMESTICALLY VIOLENT OFFENDERS: TREATMENT APPROACHES

In the United States, the judicial response to domestic violence consists of support services for victims and a combination of incarceration, court monitoring, and/or treatment for perpetrators. Treatment for court-mandated perpetrators is regulated on a state level and consists of a specified number of same-sex psychoeducational group sessions (average 26 weeks), commonly known as *batterer intervention programs* (BIPs). Although general population surveys find that men and women are equally likely to perpetrate relationship violence, men account for approximately 90% of offenders enrolled in BIPs. This is partly due to the greater physical and psychological impact that domestic assaults have on women and partly due to greater societal tolerance for female-perpetrated violence and the reluctance of male victims to call the police. This entry provides an overview of the nature and characteristics of these programs, followed by recommendations for evidence-based practice and an exploration of promising new interventions.

The most methodologically sound outcome research finds BIPs to be only minimally effective in reducing rates of recidivism. Several possible explanations have been proposed, among them the failure of existing programs to provide interventions based on best-practice models, abetted by anachronistic state standards. A comprehensive, up-to-date literature review of research on BIPs, conducted by Christopher I. Eckhardt, Christopher M. Murphy, Daniel J. Whitaker, Joel Sprunger, Rita Dykstra, and Kim Woodard in

2013, concludes that the group format has not been found to be more effective than individual, couples, or family therapy and not any safer for victims. There is also some evidence that cognitive behavioral therapy approaches work better than programs based on sociopolitical analyses of patriarchy, such as the so-called Duluth model, which is the most common BIP used in the United States.

Characteristics of Domestic Violence Intervention Programs

A 2016 survey obtained data about a range of program characteristics, domestic violence knowledge, and views on treatment and policy. Approximately half of the programs surveyed indicated that they are part of a larger counseling or social service agency. Somewhat over one third (35.6%) identified their perpetrator treatment approach primarily as Duluth, while 29.1% said that their primary orientation was cognitive behavioral therapy. Nearly all programs (97%) deliver perpetrator treatment services in the modality of group, 45% offer individual therapy, 8% offer couples therapy, and only 4% provide family therapy. Most programs meet weekly for an average of 120 min, and the average number of participants in any given group is eight.

Many of the survey questions sought to determine the extent to which BIPs meet, or attempt to meet, best practice standards. Overall, treatment providers have a poor grasp of domestic violence research, including risk factors and abuse dynamics. Whereas the scholarly literature finds that having an aggressive personality, being in an abusive relationship, and being unemployed or low income are among the most significant predictors of relationship abuse, no more than about one third of survey respondents identified these as being *very important*.

In most relationships where there is a history of domestic violence, about 60% of that violence is perpetrated by both partners; yet relatively few programs provide group participants with information or training on mutual abuse cycles. Although research indicates that men and women are equally likely to initiate relationship abuse, 86.5% of the respondents said that it is the male partner who initiates the violence, whereas 11.9%

said it was the female partner. A large majority of respondents (80.3%) said that the primary motivation for perpetrating relationship violence by men is to dominate and control the partner. In contrast, only 23.9% said that this was the primary motive for female abusers, even though the research literature finds that men and women are about equally likely to abuse partners for such a reason.

There were also some positive trends worth noting. The average assessment intake, for example, is conducted over an average period of 90–120 min, an indication that most programs do more than simply *enroll* clients. Despite one third of programs identifying as Duluth, the large majority of programs teach the emotion management and communication and conflict resolution skills found by research to be effective in reducing rates of recidivism. In this survey, 41.7% of programs have *one-size-fits-all* curriculum, a far lesser proportion than the 90% found in a previous survey, and 63.9% of programs say they adapt their curriculum to meet client needs. Finally, although most programs approve of their state standards, however flawed they may be, two thirds at least *sometimes* supplement them.

Recommendations for Evidence-Based Intervention

In 2016, an entire issue of the peer-reviewed journal *Partner Abuse* was devoted to an in-depth examination of the literature on batterer intervention, with proposals for advancing evidence-based practice. The study put forth the following recommendations on how perpetrator treatment should be conducted:

1. Interventions should be based on a thorough psychosocial assessment that addresses the needs of each individual and eschew overly confrontational tactics.
2. The treatment should be delivered by providers with accurate knowledge of domestic violence, including prevalence rates, abuser characteristics, causes, abuse dynamics, and the negative impact on victims and families.
3. The evidence is lacking as to an optimum length of treatment, and no modality has been found to be generally superior to any other. Treatment should therefore be delivered for a period of time and in a modality that is best for each particular case. There is no evidence to support current prohibitions against mixed-sex group formats.
4. Culturally focused interventions may be important for African Americans with higher racial identification. There is a consensus that in culturally focused interventions, social conditions and stressors particular to ethnic minority communities should be considered and integrated into program curricula, as well as religion and spirituality.
5. Substantially more data should be collected on the characteristics and needs of Lesbian Gay Bisexual, and Transgender populations.
6. Program content must include the information and skills with which clients can better manage their emotions, lessen stress, communicate effectively with partners, resolve relationship conflicts, and overcome trauma and other mental health issues.

Promising Treatment Directions

Therapeutic outcomes may be improved when treatment paradigms are expanded and interventions draw from the empirical research data, including the following known risk factors: (a) stress, especially from low income and unemployment; (b) having an aggressive personality characterized by a desire to dominate, hostility toward the opposite sex, or attitudes that support violence; (c) poor impulse control; (d) depression and other mental health symptoms; (e) emotional insecurity; (f) alcohol and drug abuse; (g) having witnessed violence between one's parents as a child or having been abused or neglected by them; and (h) being in an unhappy or high conflict relationship.

It is also possible that what is happening (or not happening) outside the treatment session may be just as significant as in-session factors affecting change. Clinicians have long understood that there exists a natural inclination of the brain to resist change once habits or behavioral responses are firmly established, and aggression can be a very stable personality characteristic. Given these

challenges, and research finding that homework assignments improve group retention and treatment outcomes, it may be important to consider adjunctive interventions (additional to weekly group or individual sessions) in assisting clients in developing nonviolent responses to stress and interpersonal conflict.

The review by Eckhardt and his colleagues shows that, regardless of their stated theoretical foundations, most programs combine elements of various theories, and the most successful employ some form of client-centered approach, with a focus on creating a workable facilitator–client relationship and maintaining strong group cohesion. In particular, motivational interviewing approaches can enhance the effectiveness of traditional psychoeducational–anger management hybrids. One of these, Journey to Change, developed by Deborah Levesque and colleagues and based on the Transtheoretical Model of Change, now includes a computer-based component to augment the standard batterer intervention protocol. At a 20-week follow-up, clients in one study who completed two to three adjunct computer sessions were more actively engaged in change-/help-seeking strategies (e.g., talking to clergy, medical professionals, and couples therapists for help with violence; reading self-help books). At 12 months, the same clients also reported a reduction in physical violence perpetration.

Other promising interventions may come from attachment theory. Since the early 1990s, numerous studies have demonstrated a consistent connection between insecure attachment and relationship abuse. The model proposed by Donald Dutton and Daniel Sonkin integrates these findings in the treatment of male perpetrators. It involves assessing a client's attachment style, using an established instrument such as the Experiences in Close Relationships Questionnaire, and tailoring interventions based on affect regulation strategies: self-soothing techniques for individuals who habitually upregulate emotional expression and emotion sensitization strategies for those who habitually downregulate emotion; and revising working models of self (worthiness) and others (trust) with the ultimate goal of boosting attachment security and reducing abusive behaviors. Attachment security can be contextually increased

through supraliminal (conscious) and subliminal (unconscious) priming of secure base words, images, guided imagery, and viewing the names of attachment figures. Secure base priming has been shown to reduce anger and increase self-esteem, compassion, openness to differences, flexibility, and prosocial behaviors in various populations. Dutton and his colleagues likewise found secure base priming to be effective in reducing levels of anger and anxiety in both males and females. Others have hypothesized that computer-based secure base priming exercises could be useful as an adjunct for BIPs to improve treatment outcomes (i.e., reduced psychological and physical abusiveness).

Final Thoughts

Although the domestic violence treatment field has come a long way from its early reductionist focus on traditional sex roles, current interventions have been limited to simplistic psychoeducational models that unnecessarily favor the group modality over empirically validated systemic approaches such as couples therapy and fail to properly address important developmental and psychological factors such as attachment style and motivation to change. More sophisticated and empirically based treatment models are needed to further reduce recidivism rates for both court-mandated and self-referred clients, both as primary treatment approaches and adjuncts to traditional interventions.

DOMESTICALLY VIOLENT OFFENDERS: TREATMENT OUTCOME RESEARCH

Intimate partner violence (IPV), sometimes referred to as *domestic violence* or *battering*, has received considerable attention as a societal problem and public health concern. There has been a major effort to decrease IPV through advancements in public policy and development of rehabilitative counseling programs. Pro-arrest policies throughout the United States have resulted in more perpetrators being arrested with expanded statutes that include not only physical assault but also verbal threats of harm, instilling fear through intimidating tactics, and coercive control that violates or obstructs the rights and freedom of family members. Although large-scale studies indicate that children may also be abused in about 40% of such cases, batterer intervention programs (BIPs)

have primarily focused on violence and abuse inflicted upon married, dating, or romantically involved partners, as opposed to prior programming devoted to the abusive parent. While it is well-documented that IPV can occur bidirectionally within heterosexual relationships, as well as same-sex relationships, the bulk of research on treatment outcome has focused upon male-to-female relationships.

Although perpetrators of IPV can seek help *voluntarily*, studies indicate that nearly 90% of men formally treated for IPV are court-mandated to do so. Offenders are often referred to BIPs as a component of the criminal justice response in lieu of larger fines and/or longer periods of incarceration. Fines for IPV can otherwise be indexed to \$10,000, with jail time ranging up to 1 year within many jurisdictions within the United States when charged at the misdemeanor level.

Current Treatment Approaches

With increased recognition of IPV, there has been a proliferation of intervention programs since the late 1970s. National surveys indicate that the vast majority (82%) of BIPs conduct group-based treatment, with only 5% offering individualized treatment and 13% offering some form of couples treatment to men and their partners. Although there is no empirical evidence favoring one modality over another, many clinicians cite advantages of group work such as nonstigmatizing and normalizing dynamics; cost and accessibility; and peer support to challenge and deal with denial, minimization, feelings of shame, frustration, and loss. Individual treatment is cited as helpful to address those with acute crises, mental health concerns, or presentations that might not benefit or interfere with the positive group process. Although there is empirical evidence supporting judicious use of couple formats in less severe cases, where safety can be carefully assessed and monitored, it remains a controversial issue, despite data suggesting that both partners can contribute to the initiation and escalation of violent encounters in select cases.

Although the governing philosophy and theoretical orientations of programs differ to some extent from state to state, most use a variety of psychoeducational inputs to address four aims:

(1) raising awareness regarding definitions of all forms of abuse and the legal boundaries governing intimate relationships; (2) challenging rigidly held sex roles, the abuse of power through coercive and controlling tactics, verbal and psychological abuse, and frank physical assault; (3) employing psycho-educational techniques, and other strategies, to help participants recognize and manage violence-related attitudes and angry emotions; and (4) implementing guided exercises to learn and practice nonviolent coping and conflict resolution skills. The ultimate goal of such programming is to benefit victim safety by discouraging and replacing all forms of abusive and violent behavior with total cessation of physical assault and aggression. As of 2016, 45 of 50 states in the United States have statutes dictating minimum standards for conducting such programs.

Available Treatment Outcome Studies

Initial clinical studies using within-group pre-post designs suggested that offenders who completed BIPs had relatively low rates of recidivism. The first systematic review of program outcomes concluded that offenders who completed BIPs had a significant reduction in the probability of repeated violence risk as measured by police reports. Using a public health perspective, effect sizes for recidivism reduction were reported to be comparable to those observed in medical studies of aspirin regimens designed to reduce repeat heart attacks. It was also noted that attention to dual diagnosis issues of IPV and alcohol abuse, co-occurring in as many as 40–50% of offender samples, could yield better outcomes. However, given the variable quality of research designs, and failure to observe clear dose-dependent benefit with programs of longer duration, researchers argued for more studies regarding BIP efficacy.

In a subsequent, often referenced meta-analysis, Julia Babcock and her colleagues examined over 20 studies that included minimally treated control or comparison groups and measures in addition to perpetrator self-reports. Recidivism was operationally defined as any report of physical violence by the victim partner or the presence of a police report of a similar allegation, and treatment effect size adjusted for sample size was calculated. This more stringent approach to meta-analysis yielded

small effect sizes for victim partner and police report indices (.09 and .12, respectively). No clear advantage was observed for either a gender role-based, Duluth model of intervention or a skill-oriented cognitive behavioral approach; not a surprising finding as most programs are ideological hybrids when it comes to practice. Regardless of programmatic philosophy, the impact reported for such effect sizes is rather small, as those completing a BIP would, on average, have a reoffense rate only 5 percentage points lower than individuals who receive minimal therapeutic attention, assessment, and monitoring.

However, there are many reasons why one should be cautious about concluding that BIPs are ineffective and not worthy of further study and investment. In this respect, a number of researchers have revisited the same studies examined by Babcock, with varying outcomes. By imposing more rigorous methodological standards, such as preassessment equivalence between treated and comparison groups and multivariate analysis to account for competing factors, somewhat more favorable outcomes have been found. If one considers that change could be more gradual for domestic offenders than other populations commonly treated by psychotherapeutic methods by imposing a minimum 6-month follow-up, the mean effect size has been reported to rise to .26 (moderate effect), suggesting a risk reduction of up to 20%. Some practitioners have argued that even a 5% decrease is far from negligible when translated into the lives of the over 900,000 women annually victimized by IPV in the United States.

Ed Gondolf's extended multisite evaluation is perhaps the most ambitious attempt to critically evaluate BIPs in a quasi-experimental manner. The database assembled captured a *coordinated community response* to domestic violence, whereby program outcomes were assessed in relation to the extent of criminal justice involvement, such as type of legal sanctions levied, probationary monitoring, and coordination between the legal system and treatment providers. He found that by including such predictor variables, as well as weighted statistical models to develop *propensity scores*, the estimated efficacy of program completion increased significantly for completers versus non-completers. Relative reductions in recidivism in

the range of 40–50% were found, supporting benefits associated with including BIPs as a component of a broader set of interventions. Moreover, these results were more encouraging than those reported in prior meta-analytic studies. Nonetheless, the impact is still considered relatively modest, especially when compared to effect sizes generally reported for psychotherapeutic intervention with conditions such as anxiety and depression (e.g., .85 or 70% improved).

However, it should be noted that BIP intervention is an evolving technology addressing one of society's more complex and perhaps resistant problems. Developmental psychologists have long held that aggressive conduct is a challenging behavioral problem that is prone to becoming a stable trait without early intervention. Attempts at treatment or *rehabilitation* of violent adults, even in the context of controlled and intensive prison programming, have often led to meager results. Many treatments have been tried with violent juvenile offenders, such as immersive boot camps, individual therapy, and highly evocative *Scared Straight* programs with limited and nonlasting results. Moreover, unlike the treatment of many conditions, problem reduction is still considered a failure given the fact that zero tolerance is the only socially acceptable outcome for violent behavior.

Ongoing Developments to Enhance Efficacy

Studies have indicated that existing protocols can be enhanced, to some extent, by reducing dropout, particularly among younger, less educated, and partially employed participants who are more prone to premature cessation of treatment. Although having a court-mandate for attendance can increase compliance, this is often not assured unless attended by ongoing notification of concerned victims and active monitoring by court agencies. Offering culturally sensitive versions of treatment can also decrease early dropout in programs but does not appear to enhance ultimate treatment outcomes for African American populations. Although specialized protocols have also been developed for Hispanic, Native American, and gay and lesbian offenders, there are little empirical data available regarding their comparative effectiveness. More generally, attempts to

integrate motivational interviewing principles into BIP protocols have been productive in combating client resistance, improving therapeutic engagement, advancing *readiness for change* indicated by stage assessment, increasing homework compliance, and improving mastery and retention of program concepts thought to be instrumental for desistance from violence and abuse.

However, surveys also indicate that many BIPs have failed to integrate important aspects of research into ongoing treatment efforts. Existing data support the conclusion that the group-based, *one size fits all* approach, commonly used for treating domestic violence offenders, may be inappropriate. It has been established that there are typological differences in cases commonly referred for treatment based on dimensions of severity; generality of behavioral history (e.g., family only vs. extrafamilial plus family violence); and the concomitant presence of various types of psychopathology such as antisocial, borderline, and narcissistic personality disorders.

The history of intervention with domestically violent offenders has been to essentially provide a rehabilitative disposition and alternative for the criminal justice system and an attempt to treat all comers who minimally comply. This scenario is compounded by existing standards for credentialing providers for BIPs (a bachelor's degree supplemented by specialty hours and a limited amount of supervision in many cases) that often fall short of those required for serving more compliant, less treatment resistant, and lower risk mental health populations. As a result, assessments are often limited to review of police reports, prior treatment, interview-based behavioral history, and nonsystematic risk assessment. Moreover, the average length of treatment for BIPs in the literature is around 6 months of weekly sessions totaling about 50 hr, far short of what may be necessary for treatment-resistant or high-risk offenders.

A major population study of 17,999 domestic violence offenders conducted by researchers at the University of Florida over a 10-year period with multiple follow-ups evaluated the impact of a multilevel intervention program designed to target differential program response geared to batterer characteristics. Offenders were assigned to one of three levels of treatment based on violence history as well as the presence or absence of co-occurring

problems including (1) first-time convicted, remorseful family-only offenders with no pattern of escalating coercion and control and no compounding emotional or psychiatric issues; (2) family-only offenders with repeated violence associated with a pattern of escalating power and control tactics and/or the presence of some emotional or psychiatric issues, alcohol or drug abuse, but with no history of prior domestic violence treatment failure (the most commonly referred case in Gondolf's IPV outcome studies); and (3) complex cases with serious forms of violence (e.g., strangulation, punches to the head, use of weapon, stalking, presence of serious mental health disorder), prior criminal history, probation, or protection order violations.

The overall recidivism for domestic violence across all conditions occurred at the rate of 8.4% for those individuals who completed the program compared to an overall recidivism rate of 21.2% for those who did not complete the program. Even though the study did not include a more rigorous measure of spouse/partner report, such results are promising in that it is relatively better than the 20–30% indexed recidivism rate reported by Gondolf and his colleagues for *one size fits all* approaches. However, the level of expertise required by screeners is also greater, given that a formal psychological evaluation is required to confirm a participant's placement, particularly with regard to complex cases.

In a review of over 400 studies of what is known about best practices for IPV offenders throughout the United States and Canada, it was concluded that present limitations in the efficacy of BIPs may be due, in large measure, to restrictions prematurely imposed by existing state standards regulating what can and cannot be done in terms of intervention. The authors recommended adoption of more evidence-based guidelines for intervention, as opposed to those based on preconceived ideology. A call was made for further exploration of differential treatment approaches based on typology and risk profile, expanded targets of intervention, such as faulty attachment and trauma within family of origin, and reconsideration of all treatment modalities including individualized work and properly screened, violence-specific couple intervention. If such regulation is also expanded to include support for comprehensive

assessment and ongoing program evaluation, it is possible that better treatment outcomes will result for IPV offenders and their families.

DRIVING UNDER THE INFLUENCE

Driving under the influence (DUI)—also known as driving while intoxicated in some jurisdictions, drunk driving, or impaired driving—refers to when the driver of a motor vehicle has consumed an amount of alcohol or drugs, including prescription medication that causes impaired functioning. This consumption negatively impacts processes involved in driving such as attention, sense, perception, decision-making, and execution, resulting in an increased likelihood of a traffic accident. DUI is considered a serious criminal offence in most countries and is punishable by heavy penalties including civil or criminal (although in the United States, penalties for DUI are criminal in nature).

This entry reviews road traffic injuries as a public health concern, DUI as a major risk factor for road traffic injuries, effects of DUI, strategies to reduce or prevent DUI, and methods used to detect DUI.

Road Traffic Injuries: A Public Health Concern

Road traffic injuries are an international health problem of pandemic proportions and play a dramatic role in mortality rates throughout the world. In fact, the World Health Organization has identified traumas caused by road accidents as one of the major public health problems to be tackled by countries.

According to the World Health Organization's *Global Status Report on Road Safety 2013*, 1.3 million people are killed and 50 million are injured on roads worldwide each year, with 90% of these casualties occurring in developing countries. At the current rate, it is predicted that road deaths will climb to 2.4 million by 2030. Consistent with these findings, traffic accidents are the main cause of death for men and women under 40 years of age, and it has been estimated that more than half of these deaths are related to DUI.

According to the World Bank, road accidents are an economic burden and pose a major challenge to the health-care system. The economic cost of road crashes and injuries is estimated to be 1–1.5% of gross national product for low- and middle-income countries, which is more than these countries receive in development assistance.

Thus, road accidents affect life quality, cause deaths and injuries, and have a high social and economic cost, including direct and indirect, to both society and individuals.

DUI as a Major Risk Factor for Road Traffic Injuries

Road crashes occur as a result of interactions between road and vehicle conditions, and human factors; however, approximately 90% of automobile accidents are caused by human factors (driver error).

A risk factor is defined as any attribute, characteristic, or exposure of an individual that increases the likelihood of an accident, and DUI is one of

the most significant risk factors. Available data confirm that presence of alcohol, recreational drugs, or medicinal drugs influences both the risk of an accident and the severity of sustained injuries.

Moreover, alcohol is a precipitating factor. Alcoholic beverages are widely consumed throughout the world by about 2 billion people worldwide. Thus, it is little wonder that alcohol is the most influential substance in DUI cases. Studies have shown that more than one third of adults and one half of teenagers admit to DUI at some point in their lives.

Effects of DUI

In simple terms, DUI impairs the ability to drive and increases the risk of an accident. The risk of having an accident after consuming alcohol increases exponentially with increasing concentration of alcohol in the blood. For example, every 0.8 g of alcohol per liter of blood increases the risk of an accident by 4 times. The effects of alcohol consumption on driving-related functions are modulated by some factors, such as form of consumption (regular or infrequent), expectations about their consumption, driving expertise, and driver's age. For example, a low blood alcohol level can increase accident risk for an inexperienced driver or occasional drinker intolerant to alcohol.

After drinking, the rate of alcohol absorption is largely determined by various factors including speed or rate of consumption, and alcohol type (fermented drinks such as beer or wine, or distilled beverages such as rum or whisky). Alcohol tolerance is also largely dependent on sex, age, body size, weight, and previous ingestion of food. There are also some widespread myths and misconceptions regarding how a driver can neutralize the effects of alcohol before driving, including drinking coffee, having a cold shower, or breathing fresh air. However, these are myths and only the passing of time can effectively reduce the blood alcohol level and subsequent impact.

In the scientific literature, in comparison with alcohol, less information is available regarding the incidence and prevalence of illicit substance use while driving. It is known that consuming illicit substances affects the central nervous system and that different drugs, because of their chemical

structures, affect the central nervous system differently. For example, stimulants' (e.g., cocaine, amphetamines, methamphetamines) effect on the central nervous system produces feelings of extreme well-being and increased mental and motor activity. Opiates (e.g., heroin, morphine, opium, and methadone) provide pain relief, euphoria, sedation, and in increasing doses induce coma. Hallucinogens (e.g., cannabis, LSD, ecstasy, psilocybin mushrooms) cause changes in a person's perception of reality. Such effects will impair one's ability to safely operate a motor vehicle. Available epidemiological research examining illicit drugs (i.e., other than alcohol) indicate that cannabis is the most prevalent drug detected in impaired drivers, motor vehicle accidents, and fatally injured drivers.

The combination of alcohol and illicit substance use is particularly problematic due to compounded effects significantly increasing risk of accident. A number of studies of alcohol-impaired drivers found that the majority of ethanol-intoxicated subjects presented with two or more drugs in their system.

Aside from motor vehicle accidents, DUI is also closely correlated with problematic behaviors such as road rage, inappropriate and excessive speed, failing to take safety measures (e.g., not wearing seatbelts), failing to stop after an accident, or failing to report an accident. Some of these behaviors also increase the probability of an accident and subsequent severity of injuries. Studies show that drivers are not usually aware of the risk they assume when they drive under the influence.

Strategies to Reduce or Prevent DUI

One strategy for reducing DUI is imposing consequences for instances of DUI. Legislation varies by country and even within countries (e.g., by states in the United States). In other words, there are different regulations and penalties for DUI offenses by jurisdiction. Some examples of these penalties are temporary impounding of the vehicle, a fine or mulct, driver's license suspension, community service, completion of substance abuse classes at one's own expense, or jail incarceration. In some jurisdictions, impaired drivers who injure or kill another person while driving—as well as repeat offenders—may face heavier penalties such as

prison time. Depending on the country and insurance company policies, when an accident occurs as the result of a drunk driver, insurance may not assume any responsibility for damages.

Another strategy is to enhance detection. Along these lines, a commonly used strategy is sobriety checkpoints—that is, designated traffic stops where law enforcement officers assess drivers' level of impairment. Law enforcement at checkpoints are trained in detecting not only alcohol impairment but also effects from illicit drugs.

Prevention is yet another strategy. For example, ignition interlock devices are used to prevent the operation of a vehicle by anyone with a blood alcohol concentration above a specified safe level (e.g., 0.08 mg/L). Usually, ignition interlock devices are installed in the vehicles of people with prior DUI convictions or in vehicles for professional drivers (e.g., long-haul trucks, buses).

Educational campaign and awareness communication countermeasures can effectively spread messages about the physical dangers and legal consequences of DUI. Such messages persuade people not to drink and drive and encourage them to keep other drivers from doing so. These messages also promote refusing to ride with drunk drivers and the use of safe and sober designated drivers. Complementary school-based instructional programs can be effective for teaching teenagers similar messages.

Methods to Detect DUI

To detect alcohol and other drug use among drivers, direct and indirect methods can be used. However, all methods have problems or limitations. Limits of sensitivity and precise quantification of concentrations are common problems. Procedures to combat these problems have been developed.

Detection of Alcohol

Blood alcohol concentration represents the volume of alcohol in the blood and is measured in grams of alcohol per liter of blood (g/L) or its equivalent in the exhaled air. Any amount of alcohol in the blood, however small, can impair driving, increasing the risk of accident. Therefore, the trend internationally is to lower the maximum rates allowed.

In many countries, the maximum rate of alcohol in blood allowed for a driver is 0.50 g/L and 0.25 mg/L in exhaled air. For novice drivers and professionals, the limit is 0.30 g/L in blood and 0.15 mg/L in exhaled air.

Blood alcohol concentration may be measured using three methods: breath, urine, or blood. For efficiency, expediency, and cost, breath is the preferred method for law enforcement purposes. Common problems, however, include complaints of improper testing and equipment calibration. These complaints are often used in defense of a DUI. Therefore, calls for strict controls and frequent calibration of equipment have been made.

Detection of Illicit Drugs

The principal problem with estimating *drugged* drivers has been the relative unavailability of drug detection methods or devices to routinely test suspected impaired drivers. In addition, tests to detect illicit substances in a person's system are costly. Because of the invasiveness of the collection procedure and the cost of laboratory analysis, routine screening of blood for drugs in drivers has not been practical. In some jurisdictions, though, any level of prohibited drug detected in the blood is considered evidence of DUI (*zero tolerance* laws).

Drug testing looks for traces of drugs in the body using samples of urine, breath, hair, saliva, or sweat. In saliva (oral fluid-based) drug tests, for example, a sample of the driver's saliva is taken by specially trained police officers, using an absorbent collector placed in the mouth or touching the tongue. This test takes only a few minutes to complete. The main limitation of the saliva test is that it measures some but not all drugs. If the preliminary screening for drugs test is positive, several countries, regulations require a blood test be employed as a second step.

DRIVING WHILE INTOXICATED

Alcohol-impaired driving presents unique criminal justice challenges. Drinking is legal for most adults, and driving is legal for adults with licenses. However, when alcohol is consumed in sufficiently high concentrations and combined with driving, it becomes illegal behavior. Law enforcement must target the co-occurrence of driving and drinking that poses a risk to the public. This entry discusses laws and enforcement, costs of driving while intoxicated, young adults and drinking and driving, prevention in high-risk locations, drugged driving, and future challenges.

Laws and Enforcement

Prior to the 1980s, drinking while intoxicated received limited attention from the public, policy makers, or law enforcement. In the 1980s, however, community groups such as Mothers Against Drunk Driving formed a grassroots movement to change public attitudes, laws, and enforcement. Nationwide legislation was passed to raise the minimum legal drinking age from 18 to 21 years. Also, all 50 states set .08% blood alcohol concentration (BAC) as the legal limit for driving while intoxicated (i.e., driving under the influence; drunk driving), with slightly lower levels of alcohol (.05%) combined with evidence of driver impairment leading to lesser charges of driving while impaired. For drivers under 21 years of age, a zero tolerance limit is enforced, meaning that detection of alcohol in the young driver could result in driving while intoxicated charges. These charges carry substantially heavier penalties than being charged with simply underage drinking.

High visibility enforcement coordinated with publicity regarding increased enforcement are effective strategies for reducing drunk driving and related fatalities. These strategies operate on the principle of general deterrence. Effectiveness is based upon the perceived risk of arrest for drunk driving being high, thus deterring individuals from engaging in such behavior. Ways to further reduce the injuries, deaths, and economic losses due to drunk driving are thought to be attainable by making laws more stringent (e.g., raising the drinking age to 25 years or reducing the illegal drinking limit to .05% BAC). Internationally, many countries enforce a much lower level of alcohol permitted in the body when driving (.05% BAC or lower) than the United States. Communities can reduce drunk driving by supporting a more rigorous enforcement of drinking and driving laws to maximize effectiveness. These enforcement strategies are expensive, however, and not all communities engage in sufficient levels of enforcement to sustain deterrence.

Enforcement is aimed at deterring all potential drivers who consume or plan to consume alcohol. However, a small percentage of repeat offenders contribute disproportionately to the problem. Studies in the mid-1990s showed that one in three of all arrested drunk drivers had a prior offense.

By the early 2000s, this had dropped slightly to one in four. However, drunk drivers involved in fatalities are 7 times more likely to have had a prior conviction for driving while intoxicated than are drivers involved in fatalities who had no alcohol present in their body. Repeat offenders pose a particular concern if they have diagnosable levels of alcohol that indicate alcohol dependence or alcohol abuse. In many states, there is mandatory screening for alcohol with requirements to seek treatment as part of a conviction sentence.

Costs Associated With Drinking While Intoxicated

The loss of human lives and the costs associated with injuries are real potential costs associated with driving while intoxicated. In 2014, slightly less than one third of all motor vehicle crash fatalities involved drunk drivers. In 2010, costs associated with drunk driving (e.g., injuries, insurance premiums, legal costs, productivity losses) were estimated at US\$44 billion and another US\$157 billion for lost quality of life each year. These losses occur not only for the individual engaged in the drinking and driving but also for passengers, individuals in other vehicles, and/or pedestrians. Although fatal crashes involving alcohol dramatically decreased following legislative changes in the 1980s, alcohol is still involved in about one fifth of all fatal crashes and remains an important contributor to deaths among pedestrians.

For individuals convicted of driving while intoxicated, the out-of-pocket expenses are high, with potentially serious life-altering economic consequences. Although penalties vary from state to state, consequences include fines, restitution to victims, loss of license, and possibly even jail time. Offenders also incur costs associated with increased insurance fees, court costs, legal defense fees, and time off work. Furthermore, driving while intoxicated is a felony, and having a record can negatively impact offenders' careers and life options.

Young Adults and Drinking and Driving

Younger drivers are disproportionately affected by drinking and driving. National survey data indicate that young adults (ages 18–25 years) have

higher rates of alcohol and drug use combined with driving than older adults. Of all the drivers involved in drunk driving crashes, 21- to 24-year-olds make up the largest group (30%), followed by 25- to 34-year-olds (29%). For younger and less experienced drivers (ages 16–20 years), alcohol is particularly dangerous. An 18-year-old with a .08 BAC is nearly 4 times more likely than a 24-year-old with a .08 BAC to die in a motor vehicle crash. Research from the 2010s indicates that the risks of drinking and driving for young women are on the rise.

Preventing Drunk Driving in High-Risk Locations

In addition to law enforcement strategies for deterring drunk drivers, implementing prevention strategies in environments where alcohol and drug use co-occur is important. On-premise drinking locations, such as bars, restaurants, and nightclubs, are locations for these prevention efforts. To encourage efforts to prevent drunk driving, states have passed laws increasing the liability for owners and bartenders who serve drunk patrons. Providing service to someone who is drunk can result in financial penalties to the bar owner and the bartender and can expose them to civil suits. Prevention efforts to reduce the overservice of alcohol to individuals who are already intoxicated or drunk include training for bartenders. This training covers the laws that penalize the server and owner of the bar for serving individuals who are already intoxicated. Training also includes learning how to identify the intoxicated individual and the techniques or skills needed to handle the situation.

Another prevention effort is to enlist the help of the general public in stopping drunk drivers. Public service campaigns have made major efforts to prevent drunk driving by appealing to friends to keep drunk drivers off the roads with slogans such as “Friends don’t let friends drive drunk.” When the intoxicated individual gets behind the wheel despite efforts to deter, the general public is encouraged to report drunk drivers who are on the road.

Efforts have been made to initiate prevention efforts at nightclubs where young adults congregate for entertainment and where driving to and

from the club may result in driving while intoxicated. Based upon several research studies covering a decade in the early 2000s, an estimated one in four drunk patrons exit clubs on any given night. In addition, young adults in clubs are often using marijuana and other drugs in combination with alcohol, resulting in increased driving impairment for those who drive. An estimated one in 10 patrons both drunk and on drugs leave the clubs on any given night. Furthermore, among drivers, an estimated one in five are impaired by their level of alcohol use. However, young adults in clubs who are drivers tend to drink less than their passengers and those who arrived via taxis or car ride services. This suggests that the message of *don’t drive drunk* is adopted by many young adults. Data on drug use, however, suggest a different story. There is no difference between drivers and passengers in their use of drugs, and there is some indication that driving while on drugs is not considered a driving concern. Although drivers who are intoxicated may allow a friend who is not intoxicated to drive them home in their car, drivers who are on drugs typically do not turn over their keys to a friend who has not used drugs to drive them home.

Drugs and Driving

In the late 1990s, legalized marijuana use for medical purposes emerged as a new concern regarding safety while operating motor vehicles. By 2016, trends toward legalization of cannabis for both medical and/or recreational purposes further complicate efforts to reduce risks associated with driving. Although more science is needed to determine what drugs and what levels of use create risks and increase crashes, drugged drivers are becoming more prevalent on the roadways. States that have legalized cannabis for recreational use have established rules that make cannabis use illegal while driving. However, the tools for detection and enforcement of drugged driving are far less established than they are for alcohol. When police officers stop drivers on suspicion of impaired driving, they have breathalyzers to test for the amount of alcohol present in the body and validated field sobriety tests that indicate impairment. These tests can be used to justify placing a suspected drunk driver under arrest.

These same type of tests to detect drug-impaired drivers have not been validated to the same degree. Furthermore, although such technology is currently in development, there is no accepted method for testing for the type or quantity of drug in the field.

Drugged driving risk is not limited to illegal substances. Prescription drug use is often linked to crashes. Among drivers who were involved in deadly crashes and who tested positive for drugs, nearly half of the drivers tested positive for prescription drug use. Painkillers are the most common prescription drug identified. For drugged driving, the risks are found not strictly among young drivers. For example, among drugged drivers involved in fatal crashes, approximately one in four are aged 50 years or older.

Challenges Ahead

There are a number of reasons why drugged driving is more difficult to address from a public policy and public health point of view. There are a number of different types of drugs with vastly different physical effects. In contrast, alcohol is a more uniform substance with a known level of alcohol consumed per ounce. Recreational drugs attained from noncontrolled sources may contain varying amounts of the actual drug, making it difficult to predict how the dosage will impact performance. Far more performance tests have been completed with alcohol versus all other drugs. Enforcement is easier for alcohol because there are devices that can accurately measure the amount of alcohol in the bloodstream that can be used in the field. Although drug-testing devices are being developed, field-testing for drugs lags behind the tools for alcohol assessment. As well, the public is not well informed or sensitized to the hazards of driving after consuming drugs, especially in the case of prescription drugs. Public perception of driving under the influence of recreational drugs and the need for enforcement may differ for recreational drug use versus prescription drug use. The young are disproportionately represented among the recreational drug users, and the older adults are more likely to use prescription painkillers.

Use of both recreational drugs (e.g., marijuana) and prescription drugs (e.g., painkillers) poses challenges for drivers and for communities

concerned about impaired driving. Despite those challenges, there is a clear need to expand efforts to control drunk driving and address drugged driving. A more diversified approach may be required because of the different types of substances involved, the different segments of the population affected by such prevention efforts, and the need for more precise data to determine which substances are of most concern when addressing the impaired driving problem. Finally, the impaired driving problem may look different with the emergence of the driverless and smart cars. Already, the use of devices to prevent individuals from driving while intoxicated is available. The expense of these devices limits their use to only drivers who have had convictions for driving while intoxicated. However, it is possible that a relatively low cost device for detecting impairment might become standard in cars. Also, camera and detection devices are available to detect risky driving such as traveling at high speeds, swerving, and other erratic driving behaviors. Thus, technology in vehicles may offer additional environmental prevention strategies for drunk and drugged driving.

DRUG COURTS

Approximately 60–80% of adults arrested for a criminal offense in the United States test positive for illicit drugs, and more than 40% meet diagnostic criteria for a moderate to severe substance use disorder. Continued illicit substance use is associated with a 2- to 4-fold increase in the likelihood of committing a new criminal offense. Although substance use disorder treatment can reduce recidivism significantly, only about one quarter to one half of persons referred to treatment by the criminal justice system will complete treatment successfully. Low completion rates for

treatment are attributable, in part, to the fact that only about one quarter of community treatment programs offer specialized services for criminal justice populations. Most treatment providers are untrained and unprepared to deal with justice involved clients, who frequently present with serious risk factors for criminal recidivism and treatment failure, including low intrinsic motivation for change, unstable housing, poor health care, substantial trauma histories, and aggravating co-occurring conditions such as antisocial personality disorder. This entry describes drug courts and other types of problem-solving courts designed to address the needs of this population and improve outcomes. Research findings are reviewed that demonstrate the effectiveness and cost-effectiveness of the programs and identify best practices that optimize outcomes.

Drug courts combine community-based substance use disorder treatment with continuous monitoring by criminal justice authorities and immediate and consistent consequences for treatment noncompliance. The first drug court was founded in Miami-Dade County, FL, in 1989. As of mid-2017, there were more than 3,000 drug courts in the United States and more than 1,300 other types of problem-solving courts serving persons with other social service needs, such as homelessness, mental health disorders, domestic violence, and gambling.

In drug courts, the judge serves as the leader of a multidisciplinary team of professionals, which typically includes a program coordinator, treatment representatives, clinical case manager, prosecuting attorney, defense attorney, probation officer, and law enforcement representative. Participants are required to complete substance use disorder treatment and other indicated services, undergo frequent and random drug and alcohol testing, and attend frequent status hearings in court during which the judge reviews their progress in treatment and may administer a range of consequences contingent upon their performance. The consequences increase gradually in magnitude in response to successive infractions or accomplishments in the program and may include rewards such as verbal praise or certificates of accomplishment, adjustments to the participant's treatment regimen, or sanctions such as writing assignments, community service, or brief periods of jail

detention (typically 1–5 days in duration). Successful graduates have their criminal charges withdrawn or reduced or receive a substantially reduced sentence in lieu of incarceration. Graduates may also have the arrest or conviction expunged from their legal record. Record expungement helps to avoid many of the collateral consequences associated with having a criminal record, such as a loss of voting rights or reduced access to public housing and educational loan subsidies.

Studies confirm that drug courts significantly reduce illicit substance use, reduce crime, improve participants' emotional and social functioning, and return cost-benefits to taxpayers. Studies have also identified the most effective target population of participants who should be treated in drug courts as well as a range of best practices that are associated with significantly better outcomes. In light of this success, the original drug court model has been adapted to serve other justice involved populations, such as juveniles charged with delinquency offenses, parents with serious substance use disorders involved in child abuse and neglect cases, and arrestees suffering from severe mental health disorders.

Effects

Drug courts are among the most thoroughly researched programs in the criminal justice system. Hundreds of studies published in peer-reviewed scientific journals and government-sponsored evaluation reports have confirmed that drug courts significantly reduce criminal recidivism and produce other positive benefits. Leading scientific organizations such as the Campbell Collaboration, National Institute of Justice, and U.S. Government Accountability Office have synthesized the vast body of research on drug courts in meta-analyses and systematic literature reviews. In addition, National Institute of Justice sponsored a national study of 23 drug courts called the Multisite Adult Drug Court Evaluation (MADCE). The MADCE followed over 1,100 drug court participants for 18–24 months and carefully measured program impacts on illicit substance use and other indices of participants' psychosocial functioning using saliva tests and in-person structured assessment interviews.

A consistent finding from the meta-analyses, systematic reviews, and MADCE is that drug courts significantly reduce criminal recidivism—typically measured by rearrest rates over at least 2 years—by an average of approximately 8–14%. Drug courts that received independent evaluations and concomitant training and technical assistance from experienced experts reduced recidivism by an average of 32% and by as much as 80%. The effects on recidivism have been shown to persist for at least 3 years, well after participants were discharged from the programs. Results from the MADCE further revealed that drug courts significantly reduced illicit drug and alcohol use, improved participants' family relationships, reduced family conflicts, and increased participants' access to needed financial and social services. Finally, drug courts have been determined to be cost-beneficial. Several meta-analyses and the MADCE reported that drug courts produced an average return on investment of approximately US\$2–4 for every US\$1 invested. This has translated into net economic savings of approximately US\$3,000–22,000 per participant for local communities.

Target Population

Studies indicate that drug courts do not work for everyone. The greatest benefits are derived by persons who have a moderate to severe substance use disorder and other risk factors for criminal recidivism or failure in treatment, such as prior criminal convictions, previous failures in treatment, or co-occurring antisocial personality disorder. Referred to as *high-risk, high-need* individuals, these are the persons who require the combined regimen of treatment and supervision services embodied in the drug court model. Drug courts are approximately twice as effective at reducing crime and 50% more cost-effective when they serve high-risk, high-need participants. Individuals who do not have serious substance use disorders or other risk factors for failure in treatment can be managed as, or more, effectively in less intensive and less costly programs, such as pretrial diversion, traditional probation, or a simple referral to treatment.

This finding is consistent with a general body of evidence-based principles referred to as

Risk-Need-Responsivity (RNR). Risk-Need-Responsivity is derived from decades of research indicating that the best outcomes are achieved when the intensity of criminal justice supervision is matched to participants' risk of recidivism or likelihood of failure in treatment (risk principle), and treatment focuses on the specific disorders or conditions that are responsible for participants' crimes (need principle). Requiring participants to receive too much treatment or supervision in light of their actual needs or risk level can make outcomes worse by interfering unnecessarily with their engagement in productive activities, like work, school, housekeeping, or parenting. Most important, studies indicate participants should not be mixed in the same treatment groups or residential treatment programs with higher risk or higher need peers. Mixing populations with different levels of risk or need has been shown to increase crime, illicit substance use, and other undesirable outcomes by exposing low-risk participants to antisocial peers and values. For these reasons, drug courts achieve the best results when they target their intensive blend of treatment and supervision services to persons who require those services and avoid overtreating or oversupervising persons with lower levels of risk or need.

Best Practices

Studies have reported a wide range of outcomes in drug courts. Although about three quarters of drug courts have been found to reduce criminal recidivism, a sizable minority of drug courts (about 15%) had no discernible impact on crime, and a small percentage (about 6%) were found to have increased crime. Researchers have looked carefully at what practices characterize effective drug courts and distinguish them from the ineffective or harmful ones. Practices that are consistently associated with better effects (typically 50–100% greater improvements in outcomes) are referred to as *best practices*.

Studies have found, for example, that outcomes are significantly better in drug courts when all team members attend precourt staff meetings routinely to review participants' progress in treatment, court hearings are held at least every 2 weeks for the first several months of treatment, judges spend at least 3 min interacting with

participants in court, random drug testing is performed at least twice weekly, jail sanctions are no more than a few days in duration, and participants receive evidence-based treatment matched to their assessed clinical and social service needs. These examples are by no means exhaustive, but they demonstrate how far research has advanced in defining best practices for drug courts.

Best Practice Standards for Drug Courts

Armed with empirical knowledge of what works, the National Association of Drug Court Professionals published the Adult Drug Court Best Practice Standards to guide drug court operations. The National Association of Drug Court Professionals Standards are derived from reliable scientific evidence indicating which practices produce significantly better results in drug courts and avoid harmful side effects. Responsibility for enforcing the standards is the province of state or local courts and treatment systems; however, the standards create a measurable and enforceable standard of care against which to evaluate the policies and procedures of individual drug court programs.

Adaptations of the Drug Court Model

The success of drug courts in serving adults charged with criminal offenses has spawned a wide variety of other types of drug court programs. These adaptations of the original drug court model include, but are not limited to, driving under the influence courts for individuals charged with repeated instances of driving under the influence of drugs or alcohol, juvenile drug courts for teens charged with drug-related delinquency offenses, family drug courts for parents or guardians with serious substance use disorders facing allegations of child abuse or neglect, reentry drug courts for parolees or other persons released conditionally from jail or prison who have a moderate to severe substance use disorder, and tribal healing to wellness drug courts that apply traditional Native American healing and communal practices to serve persons charged with drug- or alcohol-related violations of tribal laws.

In addition, other types of problem-solving courts have been created to address a wider range

of social service needs encountered frequently in the court system, such as domestic violence, homelessness, mental health disorders, gambling, prostitution, and school truancy. These programs deliver many, but not all, of the services delivered in drug courts, such as frequent judicial status hearings, gradually escalating rewards and sanctions, and evidence-based treatment. All problem-solving courts share a commitment to principles of therapeutic jurisprudence and believe that the courts should play a critical role in addressing some of society's most pressing ills. As the name suggests, they seek to solve problems in their community rather than simply adjudicate controversies and punish malfeasance.

Research is identifying the appropriate target populations and best practices for these newer program models, and the lessons have been similar to those learned in adult criminal drug courts. For example, studies indicate outcomes are significantly better for driving under the influence, juvenile, and family drug courts that serve high-risk, high-need participants. In addition, outcomes are better for programs that hold frequent status hearings, perform random weekly drug and alcohol testing, apply gradually escalating incentives and sanctions, limit jail sanctions to no more than a few days, and match treatment services to the assessed clinical needs of the participants. Research is ongoing to increase confidence in the target populations for these programs and identify a wider range of best practices to enhance treatment outcomes.

DRUG CRIME SENTENCING DISPARITIES

There are long-standing racial disparities in the sanctions imposed on drug offenders in the United States. However, the policies and practices pursued under the war on drugs of the 1980s greatly exacerbated these disparities and the punitiveness of drug sanctions generally. These racial disparities do not appear to be attributable to racial differences in the prevalence or frequency of drug use or involvement in drug distribution. Instead, racial disparities appear to be best explained by racial differences in the nature of drug use and drug distribution, place-based differences in drug enforcement that are correlated with race, and racial bias in the administration of drug sanctioning. There is a growing movement to change drug sentencing, and drug enforcement more generally, to reduce their punitiveness and racial disparities in drug sanctioning.

Drug Sanctions in the United States

Drug sanctioning in the United States is currently guided by policies and practices adopted under the war on drugs of the 1980s. The architects of the war on drugs asserted that implementing tough, more punitive policies toward drug law violations would suppress drug use, drug distribution, and drug-related crime. Specifically, proponents of the war on drugs persuaded jurisdictions across the United States to increase the number of drug arrests, even for low-level offenses (e.g., possession of small amounts of illicit drugs), make drug arrests and prosecutions easier by relaxing rules concerning search and seizure, and increase the punitiveness of sanctions imposed on convicted drug offenders (e.g., more prison sentences, longer prison sentences). In fact, long mandatory prison sentences have been one of the hallmarks of the war on drugs.

The clearest manifestations of this shift in drug policy are the number of offenders arrested for drug crimes and serving prison sentences for drug crimes, both of which increased sharply after the launch of the war on drugs in the mid-1980s. For instance, in 1980, prior to the war on drugs, there were approximately 581,000 drug arrests reported

to the Federal Bureau of Investigation. Yet, in 1989, that number rose to 1,362,000 and continued to grow in the 1990s and into the new millennium. Furthermore, large shares of these arrests were for possession offenses and offenses involving marijuana, which illustrates that many of those arrested were low-level drug offenders. This increase in drug arrests was achieved by law enforcement adopting a set of drug control tactics aimed at making an abundance of low-level drug arrests, such as place-based drug crackdowns, place-based *street sweeps*, buy-busts, reverse stings, controlled buys, and the use of drug courier profiles.

Not only did the number of drug offenders arrested increase, but also those arrested were more likely to be sentenced to prison—some to long mandatory terms of imprisonment. For example, for every 100 drug arrests, there were two state prison commitments for a drug offense in 1980, 10 state prison commitments in 1990, and nine state prison commitments in 2010. Similarly, the average time served for state-level drug offenses increased from 1.6 years in 1980 to 1.9 years in 2010. The federal system exhibited similar increases in drug sentencing punitiveness.

The end result of this increased punitiveness was a marked increase in number and proportion of inmates serving time for drug offenses. The proportion of prison inmates serving time in state prisons for a drug offense went from 8% in 1980 to more than 20% in the 1990s, and roughly 17% in 2016—and as of 2016, approximately 50% of inmates in federal correctional facilities are currently serving time due to a drug offense. Perhaps more telling is that state incarceration rates for drug offenses went from 15 per 100,000 in 1980 to more than 150 by 2000 and just below 150 in 2010. In short, drug enforcement and sanctioning practices implemented as part of the war on drugs dramatically increased the punitiveness of drug sanctions, lead to a marked increase in the number of inmates serving time for a drug offense, and are a major contributor to the substantial rise in the U.S. prisoner population.

Ironically, while the number of drug arrests and drug prisoners was growing, drug use was generally declining. In fact, drug use had been declining even before the war on drugs was declared in the mid-1980s. For example, past month illicit drug

use for those 12 and over dropped from 14% in 1979 to 12.1% in 1985. Drug use continued to drop after the war on drugs; by 1988, past month drug use was 7.7% of those 12 and over, 5.9% by 1993, before rebounding and then stabilizing at approximately 8.5%. Thus, while there was variation in the illicit drug use over time, the general trend in drug use was downward—even prior to the drug war. This finding suggests that changes in drug enforcement and drug sanctioning produced the growth in drug arrests and drug prisoners—not increases in the number of illicit drug users.

Racial Disparities in Drug Sanctions

The enhanced punitiveness of drug sanctioning has not affected all Americans equally. Politically and socially marginalized groups have been most affected, particularly African Americans. In fact, another hallmark of the war on drugs has been its legacy of exacerbating preexisting racial disparities. For instance, prior to the war on drugs, the drug arrest rate for African Americans was 3 times higher than that of Whites. Yet, at the height of the war on drugs (1989), this disparity in drug arrest rates rose to approximately 6 to 1 and subsequently stabilized at approximately 4 to 1.

In turn, the growth in racial disparities in drug arrests has produced differential effects on incarceration across racial groups. African Americans' rates of imprisonment have been considerably higher than those of Whites, even prior to the previously discussed policy changes. In 1980, the imprisonment rate of African Americans was 6.5 times higher than that of Whites. By 1990, this ratio grew to 6.8 before declining to 6.3 in 2000. The growth in racial disparities in imprisonment rates that occurred in the 1980s and 1990s is directly attributable to the differential effect of drug policy changes by race. As evidence, in 1999, Alfred Blumstein and Allen Beck estimated that 17% of the total growth in the number of Whites imprisoned in the United States between 1980 and 1996 was attributable to changes in drug sanctioning. By contrast, 36% of the total growth in the number of African American prisoners was the result of such changes. This finding illustrates that the increasing punitiveness of drug sanctions affected all drug offenders, yet African Americans were most affected by the enhanced punitiveness of drug sanctions.

Explaining Racial Disparities in Drug Sanctions

The available evidence indicates that racial disparities in drug sanctions are not attributable to racial differences in the *extent* of drug use or involvement in drug distribution (i.e., drug sales, drug manufacturing). Surveys measuring drug use reveal that White youth are more likely to use illicit drugs, and White youth use illicit drugs more frequently than Blacks youth. Among adults, Blacks are more likely than Whites to use marijuana but not other drugs. Race differences in drug use generally have been converged over time. Survey data assessing involvement in drug distribution are relatively rare. Yet, here again, the available evidence indicates that Whites are more likely to be involved in this kind of drug offending than are Blacks.

Three factors appear to be most salient in explaining racial disparities in drug sanctions: (1) racial differences in the *nature* of drug offending, (2) place-based differences in drug enforcement, and (3) racial bias in drug policy making and law enforcement. In regard to racial differences in the nature of drug offending, Blacks are more likely to use and sell drugs in public places and sell drugs to strangers than are Whites. These differences in the nature of drug offending are products of racial inequality; Blacks are more likely to live in urban, high-poverty areas with limited access to private space, leading to illicit drug activity taking place in public places, which in turn leads to violent disputes among drug sellers over access to these public spaces. Furthermore, public, *open-air* drug markets are often associated with other kinds of crime such as robbery, prostitution, and general disorder. By contrast, Whites' more privileged social status increases access to private spaces, and as a result, Whites' illicit drug activities are more likely to take place behind closed doors and in the company of acquaintances. The end result is that Whites' drug activities are less vulnerable to police surveillance and apprehension.

Common drug enforcement tactics focus on public drug activities and drug activity associated with violence. Police drug enforcement strategies, such as street sweeps, buy-busts, drug market crackdowns, and drug courier profiling, often

combined with consent searches, are most often employed in minority neighborhoods or places minorities frequent (e.g., bus and train stations). The greater utilization of such police tactics in minority neighborhoods leads to White and Black drug offenders having markedly different likelihoods of apprehension.

Racial bias in policy making and the administration of drug sanctions also contribute to racial disparities in drug sanctions. Some of the policies adopted as part of the war on drugs were not race neutral. Most notoriously, federal sentencing laws punished offenses involving crack cocaine, a drug associated with Black drug offenders, more harshly than offenses involving powder cocaine, a drug associated with White drug offenders. The policy makers responsible for these laws note that crack cocaine was associated with violent crime, disorder, and high addiction risks. Critics of these laws counter that the punishment gap between crack and powder cocaine offenses was too large to be justified by these factors.

In regard to the administration of sanctions for drug offenses, the relatively few empirical studies examining racial disparities in drug arrest find that these disparities cannot be completely explained by racial differences in drug offending. For example, in a 2015 study, Ojmarrh Mitchell and Michael Caudy found that there are large racial differences in the likelihood of drug arrest for African American and White drug offenders. After statistically controlling for racial differences in prior drug use, drug sales, nondrug offending, and living in high-crime neighborhoods, these racial disparities are still large, with African American drug offenders being more likely to be arrested for a drug offense than White drug offenders. Likewise, another study by these authors found that Black drug dealers had odds of arrest for drug distribution offense 150% higher than those of White drug dealers, after statistically adjusting for racial differences in drug and nondrug offending. These findings comport with the work of Katherine Beckett and colleagues who studied racial disparities in drug arrests in Seattle, WA, in 2005–2006. These authors found that Black drug offenders were much more likely to be arrested for drug offenses than White drug offenders.

In contrast to the relatively small body of research assessing racial disparities in drug arrest,

there is a sizable body of sentencing research that demonstrates that African Americans convicted of drug offenses are more likely to receive a harsh sentence than similarly situated Whites. In fact, in 2005, Mitchell found that racial disparities in sentencing for drug offenses are larger than those for either property or violent offenses. According to this study's estimate, based on 19 independent sentencing studies, the odds of receiving a punitive sentence were 40% higher for African American drug offenders than for White drug offenders.

Taken together, these studies indicate that there are sizable racial disparities in drug arrest and sentences for drug offenses. These disparities can be partially explained by racial differences in drug offending, particularly the nature of drug offending. Yet, even after taking these differences into account, there remain significant racial disparities—some of which appear to be attributable to racial bias.

Changing Paradigms

While the policies implemented under the war on drugs still dominate drug policy in most jurisdictions, there is a growing movement to abandon these policies in favor of less punitive policies and tactics. Several jurisdictions have departed from the war on drugs' emphasis on low-level drug offenses by decriminalizing marijuana (i.e., fines instead of jail time) or making marijuana offenses the *lowest priority* of law enforcement. More prominently, Colorado, Washington, Alaska, Oregon, and Washington, DC, have legalized personal use amounts of marijuana via voter initiatives. Still other jurisdictions have mandated treatment instead of incarceration for drug offenders with limited criminal histories. Notably, racial disparities in drug sanctioning have been a key issue in nearly all of these reforms. These policy changes seem to be a harbinger of larger changes in drug policies. It is difficult at this point in time to predict the exact nature of these policy changes; yet, it seems likely that the new paradigm in drug policy will focus less on punitive sanctions, focus more on drug treatment, and promote greater racial fairness.

DRUG POSSESSION

Drug possession, as a crime, is difficult to discuss because there is little standardization across the globe or within the United States on what constitutes *illegal* substances. For instance, Denmark has criminalized very few substances taken for recreation; the list of illegal substances for possession in England differs from that found in the United States; and within the United States, some states allow marijuana possession and use for recreation whereas others do not. This entry defers to the U.S. drug possession criminal code. According to Title 21 U.S. Code Controlled Substance Act, unlawful drug possession occurs when a person knowingly and intentionally possesses a controlled substance that was not provided to the person directly or in pursuit of a valid prescription order. The substance and/or the prescription order

must come from an authorized person, such as a practitioner, acting in their professional practice or under other authorized conditions.

Drug possession is different than drug distribution because illegal drug possession is most often for small amounts considered for personal use rather than large amounts for monetary reasons (e.g., trafficking, selling, and manufacturing drugs). Despite varying and vague definitions of drug possession, this entry highlights the U.S. drug schedule, theories and factors associated with drug possession and use, and discusses possession prevention efforts.

Illegal Substances

Most countries criminalizing certain substances do so along a *schedule* or continuum based on the drug's potential for dependency and abuse and the acceptability of the drug for medical uses. At the U.S. federal level, drugs, chemicals, and substances deemed illegal to possess are divided into five schedules. The lower the schedule, the lower the penalties for possession of that specific drug. The higher the schedule, the more potentially harmful the drug is viewed by the criminal justice system.

The drugs in Schedule I include heroin, methylenedioxymethamphetamine (ecstasy), LSD, methaqualone, marijuana, and peyote. Drugs in Schedule II include cocaine, methamphetamine, methadone, products with less than 15 mg of hydrocodone per dosage unit (e.g., Vicodin), oxycodone, fentanyl, Ritalin, Adderall, meperidine (e.g., Demerol), and Dexedrine. Drugs in Schedule III include anabolic steroids, testosterone, ketamine, and products containing less than 90 mg of codeine per dosage unit. Drugs in Schedule IV include Valium, Xanax, Soma, Ativan, Darvon, Darvocet, Tramadol, Talwin, and Ambien. Drugs in Schedule V are often used for antitussives, antidiarrheal, and analgesic purposes and include Lomotil, Motofen, Parepectolin, Lyrica, and products with less than 200 mg of codeine per 100 mL (e.g., Robitussin AC).

Why People Possess Illegal Substances

People may possess and use these drugs for many reasons. Cognitive–affective theories suggest that people choose to use drugs due to (a) the

perceptions and expectations of the drugs by an individual and (b) the influence of other variables, such as personality traits and how others influence them. Therefore, a person determines to use drugs based on the perceived costs and benefits of using the drug. Conventional commitment and social attachment theories are social learning theories and suggest that people learn motives and justifications for possessing and using drugs from those with whom they have emotional attachments, such as friends and family. In contrast, strain theories suggest that people may use drugs to cope with stress in society, such as joblessness and economic pressures. Regardless of theory, scientists have found some factors that are empirically associated with drug possession and use.

Many factors are associated with drug use and addiction. They vary from individuals' biology and personal experiences to their environment and perceptions of society. For instance, research shows that some people are more genetically predisposed to become addicted to drugs than others. Additionally, those who have undergone traumatic experiences, such as physical and sexual abuse, are more at risk of using drugs to cope with these experiences than those who have not been victims of these traumas. Those who live in communities stricken by poverty and drug possession commonly have a higher likelihood of possessing illicit drugs than those who live in economically prosperous communities. Biological, psychological, and sociological factors are associated with drug possession, so there is not a solitary theory that can fully explain drug possession and use in its entirety.

Despite the theoretical complexity of drug use, a continuum of illicit drug use, for which possession is essential, has been identified, and it is divided into four phases. People who are in the first phase of drug use continuum are in the *experimental phase*; they are trying a new drug. People who are in the second phase are experiencing their use being *culturally endorsed* by others, meaning the use of the drug is either accepted or refuted by users' family or friends. People in the third phase of the continuum are in the *recreational phase* in which they seek opportunities to possess and use, such as using on the weekends or holidays. Finally, people who are in the fourth phase are in the *compulsive phase*, meaning that they are psychologically dependent on the drugs they are using.

Regardless of where people are on the drug use continuum, their possession of drugs is considered illegal by the laws of the United States, and the penalties of possessing illegal drugs depend on the type and amount of drug.

Drug possession explanations are complicated by individual state laws that do not always fall in line with the federal laws. For example, as of December 2016, 28 states have medical marijuana laws in which it is legal to use marijuana for medical purposes. Recreational marijuana use is legal in the following eight states: Colorado, Washington, California, Oregon, Alaska, Nevada, Maine, and Massachusetts. Recreational use is also legal in Washington, DC. Public perceptions of marijuana and its benefits and harms have evolved over time, changing from the 1930s to 2017, so people possessing drugs in one state may be considered criminals whereas those possessing in other states are not in violation of the law.

Prevention Efforts

In the 1970s, President Richard Nixon first declared a *War on Drugs*. The goal was to eradicate the drug problem in the United States by going after *drug kingpins* (those distributing drugs). This punitive attitude toward drug suppliers created harsh penalties for drug possession in the form of long prison sentences. As this effort evolved in the 1980s, crack cocaine possession and use was seen as destroying Black communities in the country and as more dangerous than powder cocaine, even though the main ingredients are the same. A disparity resulted in which the sentencing for being in possession of the same amount of crack cocaine compared to powder cocaine was 100:1. This disparity has been attributed to racist ideologies in the criminal justice system because the majority of crack cocaine users are Black and the majority of powder cocaine users are White. In 2010, President Barack Obama's administration passed the Fair Sentencing Act in which the crack versus powder cocaine disparity was reduced to 18:1 at the federal level. Still, some believe that there should not be a sentence disparity between crack and powder cocaine possession at all. Others believe that because crack cocaine is smoked rather than simply inhaled, it is more harmful to people than powder cocaine.

The War on Drugs did not only focus on crack. Individuals were arrested for being in possession or distributing all types of drugs. Thousands of people were imprisoned for long periods of time. Even though the War on Drugs may have had good intentions, many believe that it caused more harm than good. The majority of those arrested and incarcerated during this period were users or low-level dealers, not *kingpins* or major suppliers. It also resulted in prison overcrowding, straining precious resources for crime prevention in the areas of primary, secondary, or tertiary use. The war on the supply of drugs left few resources to address the demand people had for initiating drug possession and use, intervening in possession and use before it became chronic, and preventing the spread of the demand for drugs to others.

The perceptions of drugs and drug use are constantly changing. The War on Drugs began during a time when drug possession was seen as supplying an uncontrollable threat to the well-being of U.S. citizens. This resulted in a zero-tolerance attitude toward drug use and the people who used or sold them. A good example of how the perception of drug use changes is the needle exchange program. In 1988, the government banned federal funding for needle exchange programs, in which people who use intravenous drugs could receive clean needles in order to prevent the spread of infectious diseases. In 2009, this ban was lifted briefly until 2011. People who opposed the needle exchange claim that it promotes drug use and does not address the issues surrounding people's drug use. Proponents believe that drug possession and use is a public health concern and that people are going to possess and use drugs regardless of needle exchanges, so the exchanges at least stop the spread of blood-borne diseases. The needle exchange program is considered a harm-reduction approach to drug possession and use, the goal of which is to reduce the harm associated with drug use.

As of the early 2010s, the War on Drugs, or the punitive stance on drug possession, appears to be lessening. Alternatives to the mass incarceration of drug possessors are being used to address the demand for drugs and the need for drug treatment. For instance, drug courts have been established to divert low-level drug possessors from

receiving jail or prison time. The goal is to keep people in their communities and to focus more on treatment in order to stop the revolving door of drug use and crime. This evolving perception of drug possession and use as a medical or public health concern can be connected to presidential administrations. When drug possession and use are simply viewed as crimes, there is more likely to be a War on Drugs and a focus on criminal justice agents to control the drug problem. In contrast, the more focused presidential administrations are on drug possession and use as a mental health concern, the more focus is placed on treatment and rehabilitation. Although the future of drug possession prevention efforts is uncertain, elections at the U.S. state and federal levels will direct what substances are illegal to possess and use from 1 year to the next, the penalties for drug possession, and the focus of prevention efforts.

DRUG TESTING

The term *drug testing* refers to a biological process for examining an individual to determine whether she or he may have used drugs (or alcohol) in the recent past. For criminal justice purposes, the process consists of a clinical screening conducted by a designated agent to evaluate the evidence of drug or alcohol use. There are several kinds of drug testing, including urinalysis, hair testing, blood testing, saliva testing, and breath testing.

The criminal justice system has long sought to reduce drug use among offenders, and the links between the criminal justice system and the drug treatment field are historically strong. The criminal justice system in the United States uses drug testing to measure prevalence of drug use among offenders at virtually every level of correctional custody.

In working with offenders, it is important to know their drug and alcohol use history. Many inmates have a long history of drug and alcohol use and abuse, and for those working toward offender rehabilitation, the issue of drug and alcohol use is important. Rehabilitation is particularly difficult for an individual who abuses drugs and/or alcohol. Also, research reveals a strong association between criminal behavior and violence and drug/alcohol abuse. Drug testing is a reliable means of assessing the extent to which offenders may be using or abusing drugs.

After reviewing the rationale for and methods of drug testing, this entry focuses on drug testing in the criminal justice system.

Drug Testing Versus Self-Reports

After many years of relying on self-reports of individuals in custody about the extent of their drug

and alcohol use, in the 1970s questions were raised among researchers as to the validity of self-reported drug/alcohol use. The suspicion among many was that arrestees and prisoners were underreporting their drug use. Similarly, probation and parole officers began to note that drug use was often associated with renewed criminal behavior. It was particularly troublesome because the 1960s and 1970s had been a time of rampant growth in drug use among citizens and students on college campuses. In the 1960s, heroin was most often used by criminals, but as the Vietnam War wound down and soldiers returned home, it became common to find that many had begun using heroin while in Asia. Meanwhile, marijuana, LSD, and cocaine were becoming popular throughout the country, at first in urban areas, but eventually use spread to the suburbs and, finally, even middle schools and high schools.

As a result of the increasing links between drugs and crime, the attitude of policy makers became punitive. It was well-known that drug use was typically common among criminal offenders, but it was not well-known to what extent. The advent of the Drug Use Forecasting (DUF) program in the 1980s began to provide evidence-based answers.

DUF was initiated by a National Institute of Justice fellow named Eric Wish. Wish was convinced that an objective, empirical approach to measuring drug use among offenders was needed, and his preliminary research confirmed that offenders typically underreported their drug use, when asked. He instituted a program of drug testing via urinalyses that began in New York City among jailed arrestees. Wish's research assistants approached arrestees, introduced themselves, and asked newly arrived offenders to give an anonymous urine sample. Perhaps surprisingly to some, most arrestees complied, and almost immediately, the urinalyses revealed substantially higher drug use than what then-current research—based on self-reported drug use—had previously revealed. The findings had important ramifications for the criminal justice system and local communities and jurisdictions. In 1989, the DUF program found that 76% of male arrestees tested positive for cocaine as well as 74% of those in Philadelphia and 65% of those in the District of Columbia. This was important

information for virtually every branch of the justice system. After all, not all arrestees would be imprisoned. One question that came to mind: Would drug use be even more pronounced among those who were sent to prison? After all, presumably the offenders sentenced to prison were among the worst—not the best—of all arrestees. A new era of drug testing was implemented, and the links between drug use and crime were soon more effectively established than ever before. DUF was followed by another federal program, Arrestee Drug Abuse Monitoring, and eventually drug testing found its way into virtually every branch of the justice system. This trend continues today.

Rationale for Drug Testing

Drug testing is beneficial both directly and indirectly to the criminal justice system. Not only does it measure drug use prevalence among arrestees and prisoners, it is a means of measuring the relative success or failure of drug treatment programs. Consequently, criminal justice and drug treatment professionals work collaboratively to reduce drug use among clients, many of whom end up in correctional custody or drug treatment—or both.

Drug testing facilitates the answers to questions related to contrasting models of drug treatment that have been instituted over time. Drug treatment experts frequently debate the efficacy of one drug treatment model over another. For instance, which type of drug treatment is more effective at reducing drug use and criminal behavior over the long term: abstinence-based treatment or prescription-based programs (e.g., methadone treatment)? Drug testing of those in correctional custody or treatment is an effective way of conducting ongoing assessment or follow-up for those serving their sentences or participating in mandated drug treatment—or completing their sentences or drug treatment programs.

Methods of Drug Testing

As already mentioned, there are several methods of drug testing. Each has its place, but over time, some have been found more or less useful to the criminal justice system.

Breath Testing

Police typically use breath testing when stopping a motorist suspected of driving under the influence of alcohol. Because alcohol disappears quickly from the body, urinalyses and hair testing are not practical tests for the police to use in this setting. Thus, the drug testing instrument most frequently used by police is the breathalyzer. The breathalyzer assesses the blood alcohol concentration of the motorist. The breathalyzer measures the amount of alcohol contained in the air in the lungs, as it has been established that the alcohol content of air in the lungs is a reliable indicator of the amount of alcohol in the blood stream. The breathalyzer is a valid method of measuring blood alcohol concentration, but since alcohol does not remain in the body for long, it is not effective at assessing whether or not an individual has been drinking as recently as yesterday or last week. For that reason, it is rarely used with probationers or parolees who are in the community, even those with a well-known alcohol history. Only if the clinician detects alcohol on the breath of the subject will the breathalyzer be used, although saliva testing is often preferred.

Saliva Testing

Strips or swabs are considered to be a noninvasive method to screen for drugs and alcohol in the saliva. Again, however, the issue of assessing alcohol use in previous days or weeks remains unresolved. Saliva (also known as *oral fluid*) tests can be used to test for the use of cannabis, ecstasy (MDMA), cocaine, opiates, or methamphetamines, and it can also detect certain benzodiazepines.

Blood Testing

Blood testing can be used to screen for both licit (e.g., prescription) and illicit drugs. A finger prick can be used, or a needle can withdraw blood from a vein in the arm. The blood is then examined for licit and illicit substances, including alcohol.

Hair Testing

Hair testing is an effective way of establishing over what period of time a specific drug was used.

A tuft of hair (40–50 strands) is removed from the scalp, usually the crown of the head. Chronic use of specific drugs can be detected for as long as a few months by a laboratory examination of the hair.

Urinalysis

Overall, the criminal justice system has tried many methods of biological drug testing, but urinalysis is the most frequently used. The individual is asked to urinate into a container for the initial screening. If the specimen appears to be positive for any drug, the urine is forwarded to a laboratory for analysis. Only after the lab has confirmed the results can the individual be sanctioned.

One benefit to urinalysis is that the urine test procedure can add new drugs to the testing kit, which is important in the new millennium in that many so-called designer drugs are increasingly developed and used. However, the costs associated with adding new drugs to the drug testing process are considered to be prohibitive by many jurisdictions. This means that many criminal justice subjects may be using drugs that they are not being tested for and thus escape detection.

Drug Testing in the Criminal Justice System

As already mentioned, virtually every branch of the criminal justice system uses biological drug testing to establish the extent of drug abuse among offenders, both in the aggregate and individually. Drug testing is used by the police, the courts, and corrections, including the following:

- Pretrial—Arrestees and pretrial detainees may be tested for drug and alcohol use in order to provide information to the court that may affect probation or sentencing decisions.
- Drug courts—In some jurisdictions, offenders with a history of drug abuse may be offered the opportunity to participate in a drug court where the judge or the court's designee will work collaboratively with the offender to reduce or stop drug and alcohol use.
- Probation—Many probation programs use random testing of probationers to assess whether or not they are abiding by the rules of

probation which typically forbid the use of drugs and alcohol.

- Prison-based drug treatment programs—Inmates in prison drug treatment are often treated in a segregated unit (not in the main prison population). Again drug testing is used to ensure that the offender in treatment is not using drugs surreptitiously.
- Prison population—Drug testing is often used when an inmate in the general population is suspected of using drugs or alcohol.
- Parole—Parolees are often required to participate in drug testing to ensure that they are not violating conditions of parole that require abstinence from drugs and alcohol.

Offenders are typically tested, either randomly or regularly. Probationers and parolees may be rearrested immediately or sent to treatment if they test positive for drug use. Also, many community-based criminal justice treatment programs also test the urine of clients to ensure that they remain drug free. In most jurisdictions, the drugs tested for by urinalysis include but are not limited to the following:

- amphetamines (speed, Adderall)
- barbiturates
- benzodiazepines
- cannabis (marijuana)
- cocaine
- methadone
- methamphetamines
- MDMA (ecstasy)
- opiates (heroin, pain killers)
- phencyclidine

Onsite and Offsite Drug Testing

Drug testing may be conducted onsite and offsite. Onsite means that the drug test (e.g., urinalysis) occurs following receipt of the specimen. Typically, an assigned officer or research assistant ensures that the specimen provided is from the individual being tested and that it is not adulterated in any way. The specimen is then tested via a carefully orchestrated chain of command to ensure that drug test findings are recorded and maintained. Often, if the process or specimen appears to be suspect, it is forwarded to a

preidentified laboratory, where findings are reviewed and checked, then conveyed to the sending agency.

Growing Challenges to Drug Testing Procedures

The so-called designer drugs and/or synthetic drugs pose an ever-growing challenge to biological drug testing procedures. These new varieties of drugs are multiplying and make it difficult for the developers of drug tests to keep up with the advent of new substances to test for. For those whose job is to manage drug users in the criminal justice population, the task is particularly daunting, in that most offenders turn to the new drugs as a way of subverting the drug testing process. The *traditional* drugs (listed above) have been included in most drug testing procedures for years, but the new drugs have succeeded in circumnavigating drug test results. Thus, drug courts, probation or parole divisions, and police and treatment professionals who try to measure drug use prevalence among offenders may undercount the actual number of drug users in their jurisdictions.

The Future of Drug Testing

Drug testing is not likely to disappear in the near future. As long as the problems associated with drug use continue, society has a vested interest in trying to reduce drug and alcohol abuse. Biological drug testing is an evidence-based method of providing answers and assessing drug trends and prevalence. The criminal justice system is not the only organized entity with an interest in drug testing. Others include employers, fire departments, hospitals, schools, mental health groups, scientists, and the aviation industry. Consequently, it is reasonable to infer that drug testing proponents will strive to meet the challenge of tracking new drugs of abuse and reducing the costs associated with testing for them.

DRUG TRAFFICKING

Drug trafficking can include the sale, large-scale purchase, cultivation, manufacture, processing, and transportation of illegal, addictive, and sometimes mind-altering drugs. Drug trafficking is often thought of more specifically as the illegal transportation of narcotics for profit, often from one country to another, but also within a country. It is highly profitable, in part, because governments prohibit or heavily regulate drugs. This makes them more difficult to acquire (reduces supply), thus increasing price and profits for drug traffickers. Drug trafficking is risky because law enforcement hunts for traffickers and their wares and enforces stiff penalties on those it catches, and this serves to further increase drug trafficking profitability. Organized crime groups often carry out drug trafficking. Those that make a bulk of their profits from it are referred to as *drug trafficking organizations* (DTOs). Drug trafficking is relevant to the study of criminal psychology because it is a major and highly profitable criminal activity in which criminals with various psychological motivations engage. This entry delves into the motivations for drug trafficking, trafficking methods, the role of organized crime in drug trafficking, and government strategies to combat it.

International Drug Trafficking

The United Nations has three treaties with international support that lock nations into an international drug prohibition regime. The chief United Nations body addressing drug trafficking is the United Nations Office of Drugs and Crime.

Drug trafficking has expanded with globalization. To give a sense of the size and scope of drug trafficking, the 2011 United Nations Office of Drugs and Crime report *Estimating Illicit Financial Flows from Drug Trafficking and Other Organized Crime* estimated that, in 2009, drug and transnational organized crime activities amounted to more than \$870 billion or about 1.5% of total world gross domestic product. The report further specified that drugs accounted for 17–25% of all crime proceeds, half of all organized crime proceeds, and 0.6–0.9% of world gross domestic product. According to the White House Office of National Drug Control Policy, Americans spent approximately US\$100 billion annually on cocaine, meth, heroin, and cannabis between 2000 and 2010.

Types of Drugs

The World Drug Report is United Nations Office of Drugs and Crime's annual report. The 2016 report identifies various drug types, including opioids, amphetamine-type substances, cocaine, cannabis (marijuana), and new psychoactive substances. New psychoactive substances include synthetically produced drugs (sometimes called *designer drugs*) that may be so new that they are not technically prohibited until law enforcement can detect them and work within legal frameworks to prohibit them.

Drug Smuggling Versus Trafficking

The term *drug smuggling* is often used interchangeably with *drug trafficking*. George Diaz argues in his book *Border Contraband* that a *drug smuggler* is one who smuggles prohibited goods (specifically, petty amounts for personal consumption) and a *drug trafficker* is one who smuggles professionally and at commercial scale. Other legal definitions describe drug smuggling as avoiding paying state tariffs, customs duties, and taxes, while *trafficking* is the more expansive term

relating to any activity involving prohibited drugs. Again, the terms are often used interchangeably.

Common Terms for DTOs

The most common term for an organization that traffics drugs is *cartel*, although it is widely considered by scholars to be inaccurate and deceptive. As Michael Kenney describes in his book *From Pablo to Osama*, government agencies and the media have an incentive to portray drug networks as large, threatening, hierarchical organizations, all of which the term *cartel* connotes. This, however, is not necessarily the reality nor is it technically accurate. *Cartel* is an economics term that means a number of firms that, when working together, can control the price of a commodity through the control of the supply. Drug cartels have always had competition among each other and have never been able to achieve this control over supply. Nor are they, as Kenney points out, as hierarchical as one may think. He argues that drug networks often organize themselves as flat networks that are more nimble and adaptable than traditional hierarchal bureaucracies.

Scholars use many terms for actors that traffic drugs. These include DTOs, transnational criminal organizations, drug networks, clandestine transnational actors, and organized crime groups, among many others. Street gangs, prison gangs, *maras* (large Central American gangs), mafias, and organized crime also traffic drugs.

Drug trafficking tends to be a violent business because there is no court system to resolve disputes. This makes organized crime groups that maintain a reputation for violence particularly well suited to the business. Corruption is an explanation for the resilience of drug traffickers. In Mexico, traffickers are famous for their *Plata o Plomo* strategy ("take my silver or take my lead"), which artfully describes the combination of violence and corruption used to coopt the highest levels of government.

Motivations for Drug Trafficking

Most drug traffickers and DTOs are rationally motivated by profit and act in accordance. This makes economists particularly adept at the study of drug trafficking.

Although the profit motivation appears simple and obvious, the reality is often more complex. For example, in economically unequal societies such as Mexico, many young people see drug trafficking as the only viable path to upward social mobility. For example, some young men in the Mexican state of Sinaloa (where drug trafficking has been entrenched in the culture since the 19th century as documented by Mexican scholars such as Lusi Astorga and journalist Anabel Hernandez) see drug trafficking as the only way to be respected and get young women to pay attention to them.

Some in this same society would avoid drug trafficking but are forcibly recruited under duress by organized crime groups. Some are tricked into trafficking unwittingly as *blind mules*. A mule is a drug courier often carrying smaller quantities of drugs on their body past customs agents for profit. A blind mule is a person who unwittingly traffics drugs (e.g., a smuggler places drugs in a person's bag at the airport and steals the luggage upon arrival in another location having already passed through security).

Some become drug traffickers because of the lifestyle. The Narco-Juniors of the 1990s in Tijuana were children of Tijuana's wealthy and middle class who became enamored with the *fast life*. Their dual citizenship allowed them to cross freely between the United States and Mexico with loads of cocaine and low penalties if caught with limited amounts. They glorified films such as *Godfather* and became traffickers not out of economic necessity but to live this lifestyle.

Narco Cultura

Narco cultura has become a catchall term for the cultures that have emerged around drug trafficking in Mexico and Latin America. These subcultures have many features, such as the worshipping of narco-saints such as Jesús Malverde, a possibly fictional Mexican Robin Hood bandit killed by the government for smuggling and theft, and the *Santa Muerte* or Saint Death. In Mexico, there are *narcocorridos* or drug ballads that glorify the exploits of drug traffickers. Drug traffickers who fund the construction of legitimate churches; provide cash payouts to supporters; and build roads, schools, and public works in their bases of

support sustain *narco cultura* economically. *Narco cultura* reinforces the legitimacy of criminal activity in the minds of the people who participate and benefit from it, thus decreasing the ability of authorities to stop it.

Narco-Terrorism

Narco-terrorism is an ambiguous term coined by Peruvian President Fernando Belaúnde Terry in 1983 that can refer to either the use of drug profits to support terror operations or the use of terrorism to promote drug trafficking. Insurgent actors use drug trafficking instrumentally for profit. Insurgent or terrorist actors are politically motivated and seek to overthrow or change the policy of an existing government, per the Central Intelligence Agency's definition. These groups traffic drugs to fund their terror operations, such as bombings.

There are numerous examples of insurgent groups using drug trafficking to fund their political revolutionary agendas. The Revolutionary Armed Forces of Colombia, known as *FARC* for its initials in Spanish, used profits from drug trafficking to fund its insurgent operations, which included bombings in the capital city Bogota in the early 2000s. According to *Washington Post* reporting, the Bureau of Alcohol, Tobacco, Firearms and Explosives has proven in court that Hezbollah, the Shiite terror group based in southern Lebanon, used cigarette diversion/tax evasion in the United States to fund its operations.

The Juarez Cartel of Mexico used car bombings to intimidate government officials and rivals to protect its drug business in Mexico in 2010. Pablo Escobar, leader of the Medellin cartel (Colombia), used car bombings, kidnappings of politician's family members, assassinations of government officials and police, among other tactics, to protect his drug business in the early 1990s.

Trafficking Techniques

Whatever their motivations, drug traffickers have developed ingenious techniques to traffic drugs around law enforcement. These techniques include, but are not limited to, hidden compartments in vehicles, body couriers, or mules swallowing

packets of drugs; hiding drugs inside cans of chili peppers; using fake travel documents, trebuchets, and catapults to launch drugs across borders; sea semi-submersibles (submarines); corrupting law enforcement agents to allow drugs to pass; unmanned aerial vehicles or drones, planes, go-fast boats; and more.

Fighting Drug Trafficking: Supply-Side

Policy makers and scholars conceptualize two approaches to the fight against drug trafficking: the supply-side approach and the demand-side approach. The supply-side approach focuses on targeting the supply of drugs on the logic that reduced supply will lead to decreased availability, increased price, and therefore, decreased overall use. Examples of the supply-side approach include crop eradication either by hand or by aerial spraying of herbicides. Aerial spraying has been heavily criticized in places such as Colombia because people who live near eradication sites are exposed to harsh chemicals. The primary problem with aerial spraying is that drug traffickers and drug markets are highly adaptable, and when crops are sprayed in one place, more fields simply appear in another.

Another aspect of supply-side policies is interdiction. Law enforcement can target drugs at various stages of processing or en route to consumer markets. Another form of interdiction is bulk cash interdiction. In the context of Mexican drug traffickers supplying the U.S. consumer market, drugs go north but the profits must go south often in the form of bulk cash, where police can intercept it.

Similar to interdiction, law enforcement can also target the organizations and *kingpins* (drug trafficking leaders) that traffic drugs in hopes of disrupting these markets. One common criticism of the kingpin strategy in Mexico has been that when a leader is removed, his subordinates fight for control of the organization, resulting in increased violence for the DTO and society. The lead U.S. antidrug agency, the Drug Enforcement Administration's Consolidated Priority Organization Target program, emphasized this form of interdiction in the United States and abroad. The supply-side approach has predominated the discussion from the 1970s (President Richard Nixon famously declared *war* on drugs in 1971) until the 2000s and in many ways continues through the 2010s.

Demand-Side Approach and Harm Reduction

Scholars have long argued for the demand-side approach, but this has only gained traction recently. Many studies have demonstrated the efficacy and cost-effectiveness of strategies that attempt to reduce the demand for drugs. Such strategies include drug prevention education (to prevent young people from using drugs) and treatment for drug users.

A related, but slightly different, approach is harm reduction. Harm reduction approaches attempt to mitigate the social costs of drug trafficking and use. For example, needle-exchange programs allow drug users to exchange dirty needles for clean needles, thus reducing the spread of blood-borne diseases such as hepatitis and HIV.

Alternative Policies

One way to combat drug trafficking is to consider alternatives to prohibition, such as legalization and regulation, medicalization, and decriminalization of drugs. Changing policy on marijuana in various U.S. states is a case in point. In 2012, Colorado and Washington were the first states to legalize marijuana for recreational purposes. Many others have established medical marijuana systems. These strategies, which allow legal actors to produce marijuana, have generally cut into drug traffickers' marijuana profits. Many states have also decriminalized small amounts of marijuana to varying degrees. Internationally, Uruguay has legalized marijuana, and the sitting and former presidents of Colombia, Guatemala, Brazil, and Mexico have expressed interest in alternative drug policies.

E

ECONOMICS OF CRIME

Economics of crime is a field of research comprising both positive (descriptive) and normative analyses of crime. In the descriptive part, crime is typically seen as a result of rational choices that depend on individuals' expected rewards and costs of violating the law. People are assumed to rationally choose activities, legal or illegal, that best satisfy their preferences for money, consumption, sex, excitement, revenge, and more. Just as consumers respond to changes in prices and incomes, potential offenders are assumed to respond to changes in sanctions and gains from illegal and legal activities. In empirical studies, the hypothesis that expected sanctions deter crime is tested, and the quantitative effect on crime of various possible incentives is estimated. In normative analyses, it is commonly assumed that a criminal should compensate the costs endured by society. If an expected fine is set equal to these costs, a rational potential offender will internalize the costs and society will not suffer a net loss. From a political point of view, the goal is to minimize the total costs of crime and crime prevention. An implication is to produce a balance between these costs, a balance that determines the amount of resources that should be allocated to crime prevention. This entry discusses theoretical models of criminal behavior, normative and empirical studies, methodological problems, and behavioral economics.

Theoretical Models of Criminal Behavior

Theoretical models of individual criminal behavior vary in complexity. Simple ones consider just one possible crime and simple monetary gains and sanctions. More complex models emphasize the division of time between legal and illegal activities or distinguish between individuals that are risk neutral, risk averse, and risk loving. Some models assume monetary equivalents of gains and sanctions; others do not.

The simplest models conclude that the effects of sanctions and gains are unambiguous, whereas the more complex ones do not. This diversity in results, together with discussions about rationality assumptions, has made empirical studies all the more important. In empirical studies, mostly based on aggregate data, the sanctions' effects are controlled for a number of socioeconomic factors, such as age and income distribution, benefits of crime and of legal activities, and unemployment. In almost every empirical study, an increase in the probability of arrest has a negative effect on crime, whereas the effect of changes in the severity of sanctions varies.

The Basic Model

Whereas the preventive effects of sanctions have a long history in penal policy, until the late 1960s such effects were more or less neglected in criminology and modern sociology. Then Gary Becker, who later was awarded the Nobel Prize, revitalized the ideas of English philosopher Jeremy Bentham, who had suggested that deterrence works. The

main idea is that a rational person will choose to commit a crime if the monetary gain exceeds the expected fine (the expected fine being equal to the product of the probability of being fined and the size of the fine). In such models, an increase in the probability and/or the severity of sanctions may change a crime's net gain from positive to negative, with the potential offender choosing to be law abiding. Assuming that people maximize their utility (and not their expected monetary net gain), Becker obtained the same effect for the probability of sanctions, whereas the effect of the severity of sanctions was inconclusive.

These results are general in the sense that they hold for any type of crime. Similar results are obtained in models of tax evasion, where the individual decides which proportion of income to report to the tax authorities.

Monetization of Legal and Illegal Activities

In another type of model, the individual may choose between legal and illegal activities, some of which might be boring, discreditable, exciting, or pleasant. The individual's preferences for such aspects of the activities are assumed to be monetized, which implicitly occurs if a person acts rationally according to certain axioms. If convicted, the person's income is reduced by the monetary and monetized costs of sanctions. Some individuals may choose to allocate time to both legal and illegal activities, whereas others may choose to specialize in one of them. If leisure time is fixed, an increase in either the probability or the severity of sanctions will change the optimal mix of activities, whereas such an increase may not be enough to change the behavior of an individual who has specialized in crime. For those who mix activities, an increase in the probability of sanctions will decrease the time allocated to crime, whereas the effect of an increase in the severity of sanctions is inconclusive (without further assumptions).

Various Sanctions and Attitudes Toward Risk

The model with nonfixed leisure time has been extended to include four possible criminal justice states: arrest, clear up, conviction, and serving in jail. Each justice state has its individual

probability. In such a model, the effects of gains and losses of crime, and of sanctions, are more ambiguous than in less general models. In particular, under a common assumption of attitude toward risk (decreasing absolute risk aversion), crime decreases with increasing unemployment. The reason for this result is that unemployment implies a lower income, and therefore a higher risk aversion, and thereby a lower expected utility of crime. Under risk neutrality, a change in the expected unemployment rate does not affect the time allocated to illegal activity.

If leisure time is assumed not to be fixed, an increase in returns to legal activities may increase or decrease the time allocated to both types of activities. The crucial assumption here is the individual's attitude toward risk.

If one does not accept the assumption that psychic factors associated with various activities can be monetized, such factors must be included explicitly in the individual utility functions. In such models, the effect of changes in sanctions, in individual income, and in individual costs and benefits of crime is ambiguous. Strong assumptions about individual preferences will, however, produce less ambiguous effects.

Common and Diverging Aspects of Theoretical Models

Summing up the results obtained in the various theoretical models, an increase in the probability of clear up (crime solved) or arrest has a negative effect on crime. This conclusion holds regardless of assumptions of attitude toward risk. The effect of an increase in the conviction rate for individuals who have been arrested is ambiguous. The same holds true for an increase in the probability of imprisonment for individuals who have been convicted. Reasonable assumptions about attitude toward risk will produce a deterrent effect also for these alternatives. In all, the theoretical models give some support for the probability portion of the deterrence hypothesis but less so for the severity portion.

Normative Studies

In the normative part of economics of crime, sanctions are perceived as incentives for individuals to

behave in a manner that is socially optimal. In contrast to theories of retribution, which consider the primary goal of criminal law as punishment for past actions, economic analysis focuses on how to influence potential offenders' future behavior.

In order to minimize the total costs of crime and crime prevention, one must assess the effect on crime of changes in the amount of resources allocated to the criminal justice system. Although the costs of such resources are rather easily obtained, the costs saved by a reduction in crime are difficult to assess. Some of the costs saved consist, for example, of fewer broken homes and fewer stolen cars. Other costs may be obtained by asking people how they would value reductions in specific crimes. Empirical studies include such assessments.

Empirical Studies

In empirical studies, the effects on crime of changes in various incentives are studied by using cross-sectional data, time series data, or panel data. Effects on both total crime and specific crimes are studied. Among the latter are studies on corporate crime, corruption, environmental crime, tax evasion, cybercrime, and terrorism. Evidence shows that increases in the probability of punishment produce substantial decreases in most crimes. By contrast, the effect on crime of increases in the severity of punishment is small. In particular, if prison sentences already are long, the deterrent effect of an increase appears to be negligible. One reason for this minor effect might be that many criminals have a high discount rate, which means that costs that come about far into the future are almost irrelevant. However, if the probability of sanction is high, even short sentences seem to deter.

Empirical studies of the effect of the death penalty also produce mixed results, possibly because life imprisonment may be just as scaring as a death penalty, at least in countries where death penalties are seldom carried out.

To the extent that sanctions deter, one would expect that more police would produce less crime. The results of empirical studies, however, are mixed. Indeed, most studies seem to corroborate the expected effect of more police, but some studies indicate that more police produces more crime.

The ambiguous conclusions might be a consequence of methodological problems and deficient statistics.

Methodological Problems

One of the problems in empirical studies of crime is to distinguish causation from correlation. In cross-sectional studies, it is commonly found that crime rates are low in police districts in which the probability of sanctions is high. One may too easily interpret such a correlation as an example of deterrence. The correlation might rather be caused by other differences among the police districts than differences in the probability of sanctions. If these other differences are positively correlated with the probability of sanctions, the latter can mistakenly be taken as a cause of low crime rates.

Another problem is simultaneity. Crime may depend on sanctions, but sanctions may also depend on crime. A negative correlation between crime rates and probability of sanctions cannot by itself be taken as evidence that an increase in the probability of sanctions has a deterrent effect. The correlation might be because an increase in crime will overload a police department, resulting in a decrease in the probability of sanctions.

Deficient statistics are of great concern in empirical studies of crime. It is well known that statistics on crime underestimate the true amount of crime. Also, police statistics on clear ups (number of crimes solved) and sanctions are often not correct. Such deficient data will produce flawed conclusions. Moreover, people who choose between legal and illegal acts may have poor information about the probability and severity of sanctions.

Behavioral Economics

Behavioral science consists of a literature comprising a number of laboratory experiments and other empirical studies that raise the question of the rationality assumption predominant in economic analysis of crime (and of other fields of research). Several of these studies' conclusions have resulted in generalizations of the more specific economic models of crime. As an example, laboratory experiments have shown that the choice people make is not always consistent with the assumption that

they maximize expected utility (as assumed in simple economic models). Their choices suggest that they tend to put additional weight on low probabilities of alternatives they dislike. This result is easily included in economic models of crime by substituting a weighted (higher) probability of sanction for the objective probability. Moreover, in some models, the potential criminals' subjective probability of sanction is substituted for the objective one before weighting.

EDUCATION AND CRIME

Education and crime have had a causal link to each other for as long as criminal behavior has been recorded. In fact, lack of education is a

central risk factor for predicting crime. The link is most often associated with education and employment, with employment and wages having a positive correlation with education level. To better understand the connection of education and crime, one must consider the education level of individuals who engage in criminal behavior and examine education's impact on individuals' propensity to commit criminal acts. This entry examines the correlation education has with criminal behavior and crime.

Links to Criminal Behavior

Factors that are associated with a lack of education are the same factors that are common with at-risk youth. The most prevalent factors include lack of family support, poverty, drugs and alcohol present in the home, and negative influences of peers. Poverty and education are inextricably linked, whereby education is a primary means of social mobility, enabling those born into poverty to rise in society. However, for many at-risk youth, education is compromised when they enter the criminal justice system.

At-Risk Youth

The phrase *school-to-prison pipeline* refers to the policies and practices that contribute to the funneling of juveniles from the classrooms into the juvenile and criminal justice systems. This pipeline reflects a prioritization of incarceration over education. It is hard to pinpoint the reason for the school-to-prison pipeline. Some argue that the zero-tolerance policies that were implemented after the 1999 Columbine High School massacre are too harsh, resulting in many students being overpunished for seemingly minor infractions. Others point to the emphasis placed on standardized testing scores. The students most likely to have behavior issues are often the same students who do not do well on these standardized tests.

Another theory that may help to explain the school-to-prison pipeline is social disorganization theory. According to this theory, the neighborhood environment plays a significant role in criminal activity. In general, socially disorganized neighborhoods are characterized by low socioeconomic factors, a lack of community participation, and a

lack of support in policing. In addition, such neighborhoods are challenged by multiple issues such as crime, drugs, and violence. Consequently, education may not be a priority or be adequately supported.

Impact of Education on Criminal Behavior

Education has been shown to reduce the likelihood of post-incarceration recidivism. Individuals who participate in educational programming while incarcerated are less likely to be rearrested after release from prison. The types of educational programs that are shown to be most effective are job training and basic education programming such as a high school diploma or GED. College education appears to be the most influential with regard to desistance from criminal behavior. Taking a college-level course while incarcerated not only can broaden an individual's knowledge level but also can increase his or her sense of self-esteem.

Education in Prisons

Educational programming inside of prisons varies for many reasons. The security levels of correctional facilities have direct correlation with the type of programming available. In higher security facilities, where education programming is not as high a priority as security, certain types of programs may be restricted due to a lack of resources needed to successfully implement the programs. For example, vocational programming provides technical training and teaches job-specific skills (e.g., mechanics, plumbing), but many of these programs must use tools or equipment that is restricted inside of higher security correctional facilities. Another issue affecting educational programs inside of prisons is a lack of teachers who are willing to follow the strict security conditions and constraints required in correctional facilities.

Future Outlook

Education is clearly connected to criminal behavior and crime. Whether it be education in schools or prisons, beneficial programming that is supported and productive to the individuals who

participate in it does have a direct relation to the desistance of criminal activities. Future endeavors that support education of at-risk youth, unemployed young adults, and prisoners inside of correctional facilities could have a lasting impact on the lowering of criminal activities.

ELECTRONIC MONITORING

Simply put, electronic monitoring is a technological advance to a common form of social control that has existed for centuries—house arrest. People have been restricted to their places of residence (e.g., homes, military barracks) as a condition of pretrial release, as a form of punishment and control following criminal conviction, as a condition of release during probation or parole, and as a means to emphasize and ensure treatment, among other functions. Electronic monitoring extends the conditions of house arrest by electronically tethering an individual to a generally static location, such as a residence. Early electronic devices sent repeated signals, indicating that the individual was in his or her home or within a specified distance from where the signal was generated, usually a monitoring device attached to a phone line. Current versions of electronic monitoring are more complex and versatile and will be a primary

concern of this entry following a brief discussion of electronic monitoring's origins.

Origins of Electronic Monitoring

While house arrest has been around at least since biblical time, the addition of an electronic monitor to increase surveillance is relatively new. Early experiments with technology as a form of control and rehabilitation began in the 1960s at Harvard University: Young criminal offenders volunteered to be linked electronically in a two-way system whereby they could transmit their whereabouts, as well as their perceptions and emotions, to researchers at the university. At that time, the researchers were more interested in rehabilitation than control. Specifically, following B. F. Skinner's behavioral psychological approach, their goal was to provide positive and negative feedback in an effort to promote the rehabilitation process.

Early attempts to popularize electronic monitoring did not bode well. The 1970s, however, brought about expansion of technology as a *panacea* for solving all problems, including problems associated with substantial changes in the criminal justice system. Story has it that a New Mexico state district judge (Jack Love) determined to keep nonviolent offenders out of jail was intrigued by a news story relating the use of an electronic device to monitor animals (in this case, cows) and a Spiderman comic in which a villain attached an electronic device to Spiderman to track his movements. He became convinced that such technologies could be used in the field of corrections, and he worked with numerous agencies to develop and promote electronic technology to monitor offenders outside of jails and prisons. While his efforts were not an overnight success, his work led the way to a tremendous expansion in the use of electronic monitoring, primarily through radio and phone signals, in the criminal justice system.

Early Empirical Assessment of the Effectiveness of Electronic Monitoring

Although there were a few small case studies focused on the utility of electronic monitoring, including a few conducted by Love, the first real quasi-experimental examination of a fully

implemented electronic monitoring program was based in Palm Beach County, FL, beginning in 1984. The evaluation lasted about 5 years and included follow-ups of 415 offenders electronically monitored during their probationary period. The results of the evaluation were promising, showing that virtually all (over 90%) completed their commitment on electronic monitoring and a clear majority (approximately 80%) successfully completed their entire probationary period without an arrest or revocation.

The following decades saw a tremendous overall expansion in the use of electronic monitoring. This development could be found in a variety of areas under the umbrella of the criminal justice system, including pretrial release, as a punitive intermediate sanction (more severe than standard probation and presumably less severe than straight incarceration); as a condition of release following a period of incarceration; as a method of victim protection (especially in domestic violence cases); and in combination with other intermediate sanctions such as work release, community service, or treatment (e.g., anger management, substance abuse, sex offender treatment). Along with the expansion of electronic monitoring came a plethora of studies examining its effectiveness. Outcomes for these evaluations varied from program completion to various measures of recidivism (e.g., technical violations, rearrests, new convictions, returns to custody). However, many of these studies were haphazard and not rigorous in terms of study design. Indeed, a major review of evaluation studies conducted by Marc Renzema and Evan Mayo-Wilson, published in 2005, concluded that there were few solid studies that support the effectiveness of electronic monitoring in reducing crime (i.e., recidivism). Consequently, they called for more rigorous evaluations to support the use of electronic monitoring for moderate- to high-risk offenders who might be diverted from jail or prison.

The Current State of Electronic Monitoring

Throughout the 1980s and 1990s, electronic monitoring was primarily conducted via radio signals and phone lines. Offenders were monitored primarily when they were restricted to their homes but were often allowed times when they

were not monitored, for example, on their way to and from work, during work, during treatment or counseling sessions, and for religious services. The development and proliferation of technology, especially as it related to global positioning systems (GPS), allowed for 24/7 tracking of offenders. As a result, law enforcement officers could confirm that offenders were indeed on their way to or from work; inclusion zones could be created outside the home where offenders were expected to be at certain times (e.g., at work, in treatment sessions, for family visits); and exclusion zones could be defined where offenders were forbidden to go (e.g., alcohol establishment for those not allowed to drink, schools and parks for sex offenders, and past victims' homes or work places for those convicted or on pretrial release for domestic violence offenses). At least two other technological advances have also been developed but have not been rigorously tested. First, alcohol sobriety tests can be installed on electronic monitoring/GPS units so that condition of probation or parole can be assessed at regularly scheduled times. Second, given advances in the functionality of GPS, speeding and other erratic driving patterns can be detected and acted on by criminal justice agents.

Recent and More Rigorous Outcome Evaluations

With the increase in the use of electronic monitoring, in conjunction with or without GPS, a number of systematic evaluations funded by the National Institute of Justice (NIJ) have been conducted. Edna Erez and her colleagues investigated the use of electronic monitoring with GPS for domestic violence cases. Their project was three pronged and included (1) a national web-based survey of agencies that use electronic monitoring with GPS for domestic violence case, (2) quantitative analyses of program compliance and recidivism in three jurisdictions that used electronic monitoring with GPS, and (3) qualitative analyses from in-depth interviews of key informants (e.g., victims, defendants, and criminal justice professionals) on the electronic monitoring/GPS experience. Offenders who received radio frequency monitoring had fewer arrests than those receiving no form of electronic monitoring in the

short term (i.e., during their probationary period), but there were no significant long-term (i.e., 1-year follow-up) differences detected. Interestingly, those on GPS had lower levels of program violations than those on radio frequency monitoring even though they had far more restrictions placed on them and were under heightened scrutiny via GPS tracking. Seemingly counterintuitively, the GPS group had higher rates of arrests during this period. The authors suggested that, at least in certain jurisdictions, program violations were taken very seriously and when they occurred they were met with arrests rather than simply violations of probation. In the long run, there were lower rates of rearrest among those placed on GPS than those placed on radio frequency. To summarize, the results suggest that both radio frequency and GPS tracking of domestic violence offenders can offer some promising strategies for dealing with domestic violence offenders. Finding the appropriate ways of utilizing the technology with specific types of offenders seems to be the challenge at this point.

An even larger NIJ-funded study of the effectiveness of electronic monitoring was conducted by William Bales and his colleagues at Florida State University. The study included over 5,000 medium- to high-risk offenders placed on electronic monitoring and a matched comparison group drawn from over 260,000 offenders. There was a significant reduction, approximately a 30% reduction, in failures, defined as offenders absconding or having their parole revoked, associated with electronic monitoring. GPS was significantly (about 6%) more effective in reducing absconding and revocations than straight radio frequency supervision. Importantly, the effects of electronic monitoring, while varied in level, were statistically significant across different crime types, including violent, property, drug, sex, and *other types* of offenders. The results of this study show that electronic monitoring can be a more effective type of supervision than standard parole.

Two other NIJ-funded projects focused on parolees in California. The first project focused on high-risk sex offenders following their release from prison. Then Governor of California, Arnold Schwarzenegger, signed into law that all high-risk sex offenders be monitored via electronic monitoring *for life*. Like the Florida study described

earlier, a true experimental design with random assignment was not possible, so a sample of offenders placed on electronic monitoring as they were released from prison ($n = 258$) was compared to a similar group of matched high-risk sex offenders not placed on electronic monitoring ($n = 258$). Results of the study found higher rates of program compliance and lower rates of recidivism in the 1-year follow-up. For example, sex-related parole violations were approximately 3 times higher among offenders receiving standard parole without GPS, and the overall rearrests were about twice that of those on GPS monitoring. Parole revocations and returns to custody were also significantly lower among offenders on GPS.

The positive impact of GPS on sex offender parolee outcomes and the overall success of GPS in Florida suggested that GPS may be useful for other types of offenders. Qualitative findings from interviews with parole agents using GPS technology suggested that they thought other offenders may be even more suitable for GPS supervision than high-risk sex offenders, for example, gang offenders on parole. Hence, a second project was developed and funded by NIJ to study the effectiveness of electronic monitoring with GPS for high-risk gang offenders serving parole in California.

In this study, the researchers again used relatively sophisticated matching procedures to develop an experimental electronically monitored group and a comparison group, increased the sample sizes to 362 offenders per group (total $n = 784$), and extended the follow-up time from 1 to 2 years. Researchers found that the likelihood of receiving a technical or a nontechnical violation was significantly higher among the group on GPS as might be expected, given the increased number of conditions of parole and the greater likelihood of detection given the level of supervision. Alternatively, the GPS group was significantly less likely to be arrested for any offense and specifically for violent offenses. The researchers argue that the approach taken for gang offenders emphasized suppression as opposed to treatment and rehabilitation that was the emphasis for the high-risk sex offenders. That is, parole agents use parole violations in an effort to take high-risk violent offenders off the street rather than arrests with their associated court processing costs.

Final Thoughts

At a very general level, electronic monitoring is simply a technological enhancement to standard house arrest. It is a tool that can be used for a variety of purposes including punishment and extended control over offenders at various stages in the criminal justice. However, electronic monitoring is not a panacea and cannot on its own solve all the problems inherent in the criminal justice system and, in fact, has the potential to exacerbate existing problems such as net-widening, legal issues, and having negative effects on family and friends of the defendant or offender. Some have argued that electronic monitoring, even with GPS, is nearing its *death* and will soon be replaced with other technologies (e.g., smartphones, kiosks for drug/alcohol screenings). Still, these are just other technological adaptations that, if used wisely, have much to offer the criminal justice system.

EMPLOYEE THEFT

Employee theft occurs when the employee of a business steals tangible property (e.g., cash, tools, raw materials, equipment) or intangible property

(e.g., trade secrets, designs, intellectual property) from his or her employer. This is a serious crime committed against businesses by insiders who possess specialized knowledge about the business and who have the ability to circumvent guardianship mechanisms. Although employee theft is most prevalent in places that handle numerous cash transactions, such as gas stations, corner stores, and restaurants, as many as seven in 10 businesses will experience theft by an employee. As employees engage in their normal and legitimate workplace roles, they gain knowledge of guardianship mechanisms used by the business. Employees motivated to steal use this knowledge in ways that increase the likelihood they will successfully complete their crimes. Because they are able to leverage their inside knowledge, employee thefts can persist for years undetected, with the average theft totaling more than \$150,000. This entry discusses the offenders (i.e., employees) involved in employee theft and describes several important factors that affect individual-level motivations of employee thieves.

Employees as Offenders

Employee theft is characterized by an unconventional relationship between the target of crime and the potential offender, as the offenders typically have regular and unencumbered access to their targets. Employee thieves abuse the reciprocal trust relationship that they have with their employer for their own criminal gains. The widespread nature of employee theft is due, in many ways, to the fact that the individual-level antecedents to this crime mainly develop within the organization, and the development of these deviant motivations is generally not industry-specific. Variations in industry-specific rates of employee theft are primarily due to differences in opportunity structures that exist at the industry and organization levels. When employees become motivated to engage in theft, the presence of an opportunity to steal determines whether a crime can occur. However, the development of individual motivations typically comes from factors found within the organization, and the remainder of this entry provides an overview of these individual-level factors and describes how they can influence motivations for employee theft.

Job Satisfaction

There are many reasons why deviant employees engage in theft; yet, some of the main reasons stem from the interaction of personality factors with situational issues. For example, the personality trait conscientiousness has a significant relationship with workplace deviance, including acts of employee theft. Individuals who possess low levels of conscientiousness are more likely than those high in conscientiousness to engage in counterproductive work behaviors. However, conscientiousness can also moderate the negative effects of situational factors like job dissatisfaction. This means that highly conscientious individuals who experience low levels of job satisfaction are less likely to engage in deviant acts like employee theft than are individuals who have low levels of conscientiousness and low levels of job satisfaction.

Job satisfaction refers to an individual's positive perceptions of his or her job as well as the positive emotions an employee feels about the work they perform. The term *job satisfaction* reflects a continuum of potential perceptions and emotions that range from feelings of complete satisfaction to complete dissatisfaction. When individuals reach levels on the lower end of the continuum, they are experiencing *job dissatisfaction*, which is the negative affective response to one's job performance or rewards associated with that performance. Because of its connection to employees' emotional state and their perceptions of the work environment, employees, and management, job satisfaction is considered to be one of the most important workplace factors affecting the development of employee theft motivations.

However, the specific behaviors dissatisfied employees exhibit are dependent upon the range of display options they have available to them when they choose to express their dissatisfaction. Employee theft is one of the most extreme outward and observable effects of job dissatisfaction. An employee experiencing high levels of job dissatisfaction can externalize this dissatisfaction by taking advantage of opportunities to steal from the business. Employee theft is typically the final form of outward displays of dissatisfaction a deviant employee will undertake because the seriousness of workplace deviance tends to progress as the employee becomes more and more dissatisfied.

Justice and Fairness in the Workplace

Employee perceptions of justice and fairness reflect the individual's subjective interpretations of the work environment and capture his or her interpretation of particular situations and events. Employee theft is one reaction to perceptions of unfair or unjust treatment within the workplace because of the important impact these perceptions have on feelings of job dissatisfaction. Employees who feel poorly treated are more likely to be dissatisfied with their role and may look for ways to show their displeasure that garners organizational attention and provides a feeling of intrinsic satisfaction.

The desire to arrive at a state of intrinsic satisfaction in response to dissatisfaction is most evident when deviantly motivated employees respond to feelings of inequity by choosing to steal from the business. As these employees seek to create balance between the effort they exert on behalf of the firm and the outputs they expect for these efforts, employee theft becomes a viable way to increase outputs realized without increasing input to the organization. This idea is reflected in work on strain theory and reflects the tensions that exist between employment outcomes and expectations that can lead to deviance. These feelings, particularly when occurring in the presence of antisocial peers or where there is a lack of prosocial coping mechanisms, can lead motivated employees to cope with their negative feelings through acts of employee theft.

Pay Dissatisfaction

Another form of dissatisfaction that has strong ties to employee theft is pay dissatisfaction, which is different from job dissatisfaction in that an employee may be very satisfied with their job, yet, dissatisfied with the compensation he or she receives. Because of the goal-directed nature of employment—people perform a job, in part, to receive living wages—pay dissatisfaction is one type of strain within the workplace that is highly likely to lead to feelings of anger. When an employee begins to feel this anger, he or she may be more likely to respond through deviant acts, such as employee theft, as a way to recoup perceived losses. Interestingly, when these same employees begin to feel as though the business is

compensating them properly for their efforts, the desire and motivation to steal from the business may subside. This suggests that, in certain cases, motivated employees will steal only to create balance between the value they perceive the organization receives from their efforts and the value of the compensation they receive from the business.

A potential response to differences between employee expectations and pay realities is for businesses to shape employee expectations of the rewards they should expect to receive, which may have an effect on employees' perceptions of pay parity. When this occurs, the employees' pay will remain the same, yet their relative pay expectation will likely shift so that they are willing to accept pay conditions that might otherwise have contributed to the motivation to steal. However, as with issues of job dissatisfaction, employees will likely engage in a range of deviant workplace behaviors in response to feelings of pay dissatisfaction. As a result, attempts to reach the point of employee perceived pay parity may reduce the occurrence of theft but may have no impact on other types of workplace deviance, such as loafing and absenteeism. Because pay dissatisfaction is often relative in nature, employee theft may be viewed as an extreme reaction to the employee's dissatisfaction with his or her pay.

Role Stressors

As with the other business-based factors leading to employee theft, role-based stressors specific to an individual employee may influence the development of counterproductive behaviors. Stress in the workplace can develop from a number of different sources, including a poor fit between the employee and the job he or she is asked to do, issues within an employee's work group, or from general problems occurring within the company. Just because there is a poor fit between the employee and the business does not necessarily mean that employee theft will occur. Instead, as with pay and job dissatisfaction, a series of outcomes are possible, with employee theft being just one potential response to stress.

Role-based stress can also develop when employees feel the business has violated informal agreements, also known as *breaches of implicit*

relational or transactional contracts. Employee theft can result when the negative feelings result from the violation of informal agreements based upon trust and important interpersonal relationships. Importantly, the quality of these relationships and the importance of the informal agreement have an influence on the types of workplace behaviors an employee displays. A breach of implicit or perceived informal contracts also has the potential to create stress because, at times, contract breach is a signal to the employee that his or her contributions are not valued or respected. In these instances, the employee may feel higher levels of job dissatisfaction, experience feelings of injustice, and perceive greater amounts of unfair treatment in the workplace.

Psychological Ownership

Employees who commit themselves to the business and invest large amounts of physical, cognitive, and emotional energy toward the accomplishment of organizational objectives can come to feel a sense of ownership over the business or business outputs. Generally, these feelings of psychological ownership lead employees to feel strong connections to the organization, leading them to exert effort to protect the organization from harm. However, it is possible that employees who have made what they perceive are unrecognized yet significant contributions to the organization become motivated to steal from the business. As a result, the potential positive benefits gained from increasing an employee's perceptions of psychological ownership are turned into motivations to engage in serious forms of organizational deviance.

Employee theft that occurs in cases when employees feel strong levels of ownership and a strong connection to the business may stem from a desire to create parity between expected outcomes and perceived inputs. Accordingly, feelings of psychological ownership may be tied to issues of justice and fairness, where employees who feel high levels of psychological ownership take less note of justice and fairness issues because they receive some other form of intrinsic satisfaction from their work. This intrinsic satisfaction may also lead these employees to identify more closely with the tangible outcomes of their organizational contributions, leading them to see theft not as a form of

deviance but rather as a way to regain ownership of property they already view as their own.

Theft Reduction

Employee theft is a common occurrence, and no business is immune from this crime. The individual-level factors that lead to the development of theft intentions are found within every industry, as such they provide a common benchmark from which to address theft prevention. Although each industry and business will have structural and operational factors that affect opportunities for theft, the individual-level factors discussed in this entry cut across organizational boundaries. Therefore, these factors represent commonalities that, when leveraged properly, can lead to theft reduction strategies that are not specific to any particular organization.

ESTIMATE OF RISK OF ADOLESCENT SEXUAL OFFENSE RECIDIVISM (ERASOR)

The Estimate of Risk of Adolescent Sexual Offense Recidivism (ERASOR) is a risk assessment tool using a structured professional judgment approach. Instruments like the ERASOR attempt to help evaluators make a decision about sex offense risk (low, moderate, or high). All good tests and instruments attempting to measure human behavior must be valid and reliable. Risk assessment tools must measure what evaluators want to measure (validity), and they must allow evaluators to generate a measure that can be repeated over time, with others coming to the same conclusion (reliability). However, risk assessment with adolescents is more dynamic and changing, so risk assessment may be best looked at as a process that can guide efforts at intervention, treatment, and management.

The ERASOR seeks to allow a trained evaluator to meaningfully combine psychosocial, statistical, factual, and environmental information in a way that allows for responsible and defensible decisions about risk management as well as treatment and placement, if applicable. The ERASOR permits an evaluator to come to a decision about an assessment of risk for reoffense. It also can assist an evaluator to create and develop a plan for treatment and can identify areas where the adolescent might require some motivation to accept and engage in treatment. This entry discusses several general considerations in sex offense risk with adolescents.

Risk must be measured so that professionals can determine how best to intervene, treat, and manage risk and associated factors. With an adolescent, a professional trying to measure risk—because risk factors are often more fluid—is encouraged to measure risk at different points. The adolescent can be assessed after being charged

with a criminal offense, once detained and provided counseling or other treatment measures, and again after treatment and adjudication have occurred. Adolescent sex offense risk assessment is a process that can be used to determine the type and intensity of treatment needed and to help define goals and objectives (*targets*) of treatment and case management.

With adolescents, however, there are issues complicating sex offense risk assessment. The first are base rates. A base rate is the rate at which a behavior (e.g., sexual assault) occurs in the general population of adolescents. These base rates for juveniles are relatively low. So, when trying to measure or assess the likelihood of another sex offense occurring, evaluators can be prone to *inflating* their assessments because the base rate of the behavior is so low to begin with. This can lead to the perception of a higher probability of risk than is actual, a serious error. Another factor complicating risk assessment is that nearly all of the existing research is based on experience with adolescent males. The data on female sex offense risk are emerging.

The ERASOR is a relatively short-term (less than 1 year) risk assessment tool to be used with adolescents between the ages of 12 and 18. It allows for a consideration of both static (fixed and historical) and dynamic (changeable, amenable to treatment) risk factors. The second version, ERASOR 2.0, has 25 items across five relatively self-explanatory areas: sexual interests, attitudes, and behaviors; historical sexual assaults; psychosocial functioning; family/environmental functioning; and treatment considerations. The factors considered (not a complete list) include having two or more victims and whether one is a male, attitudes supportive of offending, threats or use of violence, and peer relations and social isolation. Because the emphasis is on short-term assessment of sex offense risk (very prudent with adolescents), the ERASOR 2.0 is also recommended to be utilized as a repeated risk assessment to evaluate changes over time.

Adolescent sex offense risk assessment with tools like the ERASOR focuses not only on adolescents who commit sexual offenses but also on the systems within which they live and function and upon those whom they depend for nurturance and guidance. In short, risk assessments with

adolescents seek to place behavior and risk factors in the context of the social environment and human development. With adolescents, because these factors are very dynamic and changing, the assessment of sex offense risk is also considered to be time limited.

The ERASOR is considered to be an *empirically guided* instrument, not a true actuarial tool. Therefore, an assessment using the ERASOR does not have cutoff scores. However, the research continues to grow, indicating that the reliability and validity of the ERASOR is improving judgments of adolescent sex offense risk assessment. A prominent feature of the ERASOR is its inclusion of dynamic, or changeable, risk factors, making evaluations using the ERASOR especially helpful in intervention planning for adolescents and to make adjustments to case management plans as they evolve.

However, despite an evolving base of research regarding the validity of common risk factors for adolescent sexual reoffending, the knowledge is theoretical and conditional; there is not definitive evidence regarding risk factors for sexual recidivism in adolescents. It is also likely that complex interactions among different risk factors are at play at different times in the development of children and adolescents and that these dynamics are exceptionally difficult to disentangle and document empirically. Similarities found between risk factors and other problem behaviors, including general antisocial conduct, complicate matters even further.

The ERASOR 2.0 has not been as widely examined as have some other measures of adolescent sex offense risk, but like others, assessments using the ERASOR are not considered to lead to findings that can be considered strongly predictive regarding sex offense risk. The ERASOR also employs only a clinical rating system based on the evaluator's judgment of risk associated with the presenting risk factors (e.g., it does not allow for a more precise assessment of risk such as one that might be obtained using an actuarial method).

Although risk factors are the foundation of virtually all risk assessment instruments, in recent years, more attention has been given to protective factors and their role in mitigating risk. The role of protective factors in juvenile delinquency prevention has long been recognized. Their appearance in the sex offense risk literature and their consideration in the process of evaluating

adolescent sex offense recidivism is relatively new. Attention must be paid to the possibility of factors that protect against antisocial conduct as well as to those that predispose to it. Similarly, it is critical to understand factors that suggest the absence of offending behavior as well as those that suggest reoffending and the moderating effects that protective factors can have.

Perhaps most important, findings from risk assessment with instruments like the ERASOR must be integrated into a comprehensive assessment process that produces a thorough understanding of the adolescent being assessed. With adolescents, the value of sex offense risk assessment can lie in a consideration of dynamic risk factors that might serve as a basis for case management rather than in the capacity to accurately predict risk. However, it has been shown that different raters using the ERASOR can significantly differentiate repeat adolescent sexual offenders from those who do not reoffend.

However, evaluators using the ERASOR 2.0 to assess the potential for adolescent sexual offending behavior should consider evaluations with the instrument as one part of an ongoing process. It should also be a process involving contributions from many professionals involved in the adolescent's life (e.g., teacher, probation officer). Any assessment using the ERASOR 2.0 is strengthened when it considers multiple sources of data. Adolescent sex offense risk is one aspect of an adolescent's behavior at a particular point in time. The ERASOR 2.0 is a tool that should be used, as indicated, as one part of a comprehensive assessment process that looks at the factors involved in this behavior which change over time, like the adolescents themselves.

EVIDENCE-INFORMED TOOLS FOR ASSESSING CORRECTIONAL REHABILITATION PROGRAMS

By conducting controlled studies, researchers are able to determine if a correctional program is effective in reducing recidivism. Through years of research, there has emerged a large body of knowledge that has identified the characteristics of effective correctional rehabilitation programs. This research is often referred to as the *what works* literature. Programs that have demonstrated reductions in recidivism have certain attributes, which in turn have led to the development of several tools designed to assess and measure the degree to which correctional programs are consistent with the research. In some ways, the process of correctional program assessment is similar to the assessment of an offender: Research is conducted, and risk factors are identified, then an assessment tool is formulated, and a process is followed to examine the characteristics of the offender to determine his or her risk of reoffending. Factors, including prior record, substance use, employment history, attitudes toward the crime or victim, whom the offender spends time with, and other factors that have been found through research to be related to the probability that the offender will or will not recidivate, are examined through the risk assessment process. In the case of a correctional program assessment, the principle is the same, except rather than look at an individual offender, the process assesses a correctional program to determine if the program has certain characteristics (e.g., strong leadership, qualified

staff, sound assessment processes, use of effective treatment model, quality assurances in place) that have been identified through research to be related to reductions in recidivism. This entry provides an overview of evidence-informed tools for assessing correctional rehabilitation programs, namely, the Correctional Program Assessment Inventory (CPAI) and the Correctional Program Checklist (CPC), and explores the purpose, scoring, limitations, and benefits of these tools as well as the findings related to their use.

Development of Correctional Program Assessment Tools

As a challenge to those who believed that correctional rehabilitation was not effective, a group of Canadian scholars began to look more closely at the evidence and to identify some key principles that needed to be followed in order for the correctional programs to be effective in reducing recidivism. Led by Canadian psychologists Don Andrews, Paula Gendreau, and James Bonta, some key principles were identified and became known as the Risk-Need-Responsivity (RNR) model. The essence of the RNR model is that in order to be effective in reducing recidivism, correctional programs need to focus on higher risk offenders (Risk), target the major criminogenic needs of offenders (Need), and deliver program and services based on cognitive behavioral and social learning theories that address individual learning styles and the barriers that program participants often face (Responsivity). The emergence of the RNR model led to the need for a program assessment tool to better gauge the degree to which correctional programs were adhering to the model.

CPAI

In the 1980s, Paul Gendreau and Don Andrews developed the CPAI. This tool was designed to assess a correctional rehabilitation program to determine the degree to which it was consistent with the RNR model and the principles of effective intervention. The CPAI was based on the clinical experience of the authors as well as a large body of research, including the results of meta-analytic reviews that demonstrated that correctional programs could be effective in reducing

recidivism. The original CPAI consisted of 65 items in six basic areas: Implementation, Staff, Offender Assessment, Treatment, Evaluation, and Other. Each item was scored, and an overall rating was obtained. Over the years, the CPAI has been used to assess hundreds of correctional programs, and there are now several versions of the tool.

CPC

Using the CPAI as the foundation for additional studies, researchers at the University of Cincinnati conducted several studies involving over 45,000 offenders and several hundred correctional programs. This research led to the development of the evidence-based CPC. Through these studies, the researchers were able to validate specific items and to identify new items that were significantly correlated with reductions in recidivism.

The CPC is divided into two basic areas: content and capacity. The capacity area is designed to measure whether a correctional program has the capability to deliver evidence-based interventions and services for offenders. There are three domains in the capacity area: Program Leadership and Development, Staff Characteristics, and Quality Assurance. The content area includes the Offender Assessment and Treatment Characteristic domains, and it focuses on the extent to which the program meets certain principles of effective intervention. There are a total of 73 scored indicators, and programs are rated as either *Very High Adherence to Evidence-Based Practices (EBP)*, *High Adherence*, *Moderate Adherence*, or *Low Adherence*. Over the years, researchers have conducted approximately 1,000 assessments of various programs, including those serving adults and juveniles across a wide range of settings such as prisons, residential programs and halfway houses, outpatient settings, probation and parole agencies, and court programs. The CPC is now used by a number of states and correctional agencies to assess their programs. There have also been several new versions of the CPC created for use in different types of correctional settings, allowing for increased specification for commonly seen offender treatment programs. These include versions for assessing stand-alone groups, drug and mental health courts, and community supervision agencies.

Purpose of Program Assessments

Tools such as the CPAI and the CPC have several purposes, including:

- evaluating the extent to which correctional treatment programs adhere to the principles of effective intervention;
- providing feedback that can be used for program development and improvement;
- providing a tool to assist correctional agencies in monitoring program integrity and helping ensure quality delivery of services provided to offender populations;
- assisting agencies in evaluating and selecting service providers for funding; and
- stimulating research on the effectiveness of correctional treatment programs.

Conducting Program Assessments

Conducting program assessments combines a qualitative and a quantitative process. Information is gathered through structured interviews, group observations, and reviews of materials, and it is then scored following a detailed scoring guide. Both the CPAI and the CPC assessment processes require a site visit to collect program information. These include, but are not limited to, interviews with executive staff (e.g., program director, clinical supervisor), direct service delivery staff, and key program staff; interviews with offenders; observation of direct services; and review of relevant program materials (e.g., offender files, program policies and procedures, treatment curricula, client handbook). Once the information is gathered and reviewed, the program is scored and ratings are given. The program also receives a detailed report that identifies the strengths of the program (i.e., areas that are consistent with the research) and the areas that need improvement (i.e., areas that are not consistent with the research). Recommendations are also made which essentially provide a road map for program improvement.

Limitations of Program Assessments

There are several limitations to the CPAI and CPC that should be noted. First, these instruments are based upon an *ideal* program; that is, the criteria

have been developed from a large body of research and knowledge that combines the best practices from the empirical literature on *what works* in reducing recidivism. As such, there is no perfect program. Second, as with any explorative process, objectivity and reliability are an issue. Although steps are taken to ensure that the information gathered is reliable and accurate, given the nature of the process, decisions about the information and data gathered are invariably made by the assessors. Third, the process is time-specific. Changes or modifications may be planned for the future or may be under consideration; however, only those activities and processes that are present at the time of the review are considered for scoring. Fourth, the process does not take into account all of the *system* issues that can affect the integrity of the program. Finally, the process does not address the reasons that a problem exists within a program or why certain practices do or do not take place. Rather, the process is designed to determine the overall integrity of the program.

Advantages of Program Assessments

Despite these limitations, there are a number of advantages to the process. First, it is applicable to a wide range of programs. Second, unlike a traditional audit process that often examines a program based on some derived standards that are not necessarily linked to outcomes, the CPAI and the CPC are based on a large body of empirical research, and in the case of the CPC, all of the indicators have been found to be correlated with reductions in recidivism. Third, the process provides a measure of program integrity and quality; it provides insight into the *black box* of a program, something an outcome study alone does not provide. Fourth, the results can be obtained relatively quickly; usually the site visit process takes a day or two, and a report is generated shortly after. Fifth, the program assessment process identifies strengths and areas that need improvement as well as specific recommendations that will result in the program more closely adhering to evidence-based practices. Finally, it allows for benchmarking. Comparisons with other programs that have been assessed using the same criteria are provided. Since program integrity and quality can change over time, this process

also allows a program to reassess its adherence to evidence-based practices.

Findings From Program Assessments

The results from program assessment conducted throughout North America and several other countries have revealed that there is still a great deal of work to be done when it comes to improving correctional programs. Data from hundreds of assessments (both CPAI and CPC) indicate that only about 25% of all programs that have been assessed would be considered as adhering to the principles of effective intervention. While many programs have strong leadership and qualified staff, the areas of offender assessment, treatment, and quality assurance still need improvement.

EXHIBITIONISM

Exhibitionism is commonly defined as exposing one's genitals to unsuspecting strangers in public places for purposes of sexual gratification. It is one of eight paraphilias included in the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*. Paraphilias are defined in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* as persistent, intense, and atypical sexual interests, and these are thought to be highly comorbid. In other words, the presence of one paraphilia, such as exhibitionism, increases the likelihood that other atypical sexual interests or paraphilias will also be present. For instance, research conducted by Kurt Freund and colleagues in the 1908s, which examined a large sample of male exhibitionists referred to a psychiatric teaching hospital for paraphilic behaviors, revealed that many of these exhibitionists also admitted engaging in voyeuristic activities (e.g., watching others in a state of undress or engaging in sexual activity) or frotteurism (e.g., touching or rubbing against a nonconsenting person for sexual purposes)—40% and 34%, respectively. High comorbidity with telephone scatologia (i.e., obscene telephone calls) has also been reported in additional research studies which may not be surprising given this behavior, like exhibitionism, also has unsuspecting victims and does not involve physical contact.

After providing background information on exhibitionism, this entry focuses on its conceptualization as a psychiatric disorder, including prevalence and implications with regard to criminal behavior, risk and recidivism, and treatment.

Background

In 2004 at the annual championship of the National Football League held in Houston, TX, the New England Patriots defeated the Carolina Panthers by a score of 32–29. At the time, this game was called “the greatest Super Bowl of all time.” Today, it is perhaps more well known for its controversial halftime show in which a *wardrobe malfunction* resulted in the exposure of celebrity singer Janet Jackson's right breast. Following this incident and just before the start of the second

half, Mark Roberts, an infamous British streaker who has run naked during several international events, ran on to the field disguised as a referee, undressed, and performed a little dance wearing only thong underwear before being arrested for trespassing.

Events such as these involving the public exposure of body parts that are not normally exposed, such as the breasts, buttocks, or genitals, have been recorded since classical times. In a well-known legend dating back to the 13th century, English noblewoman Lady Godiva was said to have rode through the streets naked, covered only by her long hair, in protestation of her husband's oppressive taxation practices. However, the exposure of sexual body parts in public was first conceptualized as a psychiatric disorder in 1877 by French physician Charles Lasègue. But when does such exposure become *indecent* or *disordered*? Is the *accidental* exposure of a right breast to millions of unsuspecting television watchers *indecent*? Are those individuals who are called *streakers* psychologically *disordered*?

The answers to such questions are complex and may depend on the jurisdiction (e.g., local laws and social customs) and circumstances in which sexual body parts are exposed (e.g., public vs. private settings), including to whom (e.g., consenting adults or nonconsenting individuals including children or minors) and for what purpose (e.g., for sexual gratification or some other reason such as reducing taxes), as well as any resulting consequences (e.g., harm caused to self and/or others). Collectively, these may be all exhibitionistic behaviors—a term derived from the Latin *exhibere* meaning to display. However, the term *exhibitionism* is usually reserved for a subset of these behaviors involving sexual fantasies, urges, or behaviors.

Prevalence and Diagnostic Considerations

The prevalence of specific paraphilias, including exhibitionism, is difficult to estimate. Paraphilic behaviors are often underreported by both victims and perpetrators. Prevalence rates also vary by setting with forensic and clinical samples having higher rates than community samples. In one of the largest community surveys conducted to date comprising 2,500 randomly selected adults in

Sweden, approximately 4% of men and 2% of women reported engaging in exhibitionistic behavior. However, only male gender was associated with *paraphilia-like* behaviors, which supports the notion that males are more likely to engage in exhibitionistic behaviors and to meet criteria for exhibitionism than are females. For this reason, offender samples are predominately male. Classic research conducted by Gene Abel and colleagues in the late 1980s found prevalence rates of 25% for exhibitionistic behavior in a sample of nonincarcerated sex offenders. Moreover, each exhibitionist reported having hundreds of victims. More recently, in 2003, Judith Becker and colleagues found that 14% of sexual offenders petitioned for sexually violent predator commitment in Arizona met criteria for exhibitionism. In comparison, only 5% met criteria for frotteurism. Such research provides further confirmation for the litany of studies that have identified exhibitionism as one of the most common paraphilias and sexual offenses.

A pattern of exhibitionistic behavior repeated to obtain sexual satisfaction may also constitute a psychiatric disorder. In order to meet *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* criteria for exhibitionistic disorder, exhibitionistic fantasies, behavior, and/or urges must occur over a significant period of time (e.g., 6 months) and cause harm (e.g., feelings of distress). Specifically, the exhibitionist may experience self-harm as a result of exhibitionistic behavior (e.g., mental anguish) and/or may inflict harm upon others as a result of this behavior (e.g., violation of legal rights).

Exhibitionism has also been conceptualized as a *courtship disorder* in which one of the phases of courtship, dating, or partner-based sexual interaction is extremely intensified and disordered (in this case the pretactile interaction phase), while others are omitted (e.g., sexual intercourse). However, studies have not fully supported this hypothesis and it has been debated whether exhibitionistic behavior may be an invitation or replacement for sexual intercourse.

The extent to which those who perpetrate exhibitionistic behaviors are *sexually deviant* has also been debated. Deviant sexual arousal is most commonly evaluated via phallometric assessment in which changes in penile circumference in response

to visual or auditory stimuli are measured using a strain gauge. In a 1991 matched study of men convicted of indecent exposure and men with no history of indecent exposure conducted by William Marshall and colleagues, those in the exhibitionist group displayed greater arousal to scenes of exposing than nonoffenders, but the actual degree of deviant preference was not marked. (In this study, the offenders had exposed themselves to an average of 18 people each, all adult females.) It has been argued that seemingly counterintuitive and mixed findings in this area could be attributed to small and diverse samples. However, Marshall and colleagues also found that phallometric responses to exposing scenarios were not correlated with reoffending. More recently, there have been data to suggest that exhibitionists may be *hypersexual* or sexually compulsive.

Exhibitionistic Behaviors and Impacts

The majority of exhibitionistic behaviors occur in urban areas—on public streets, public parks, parking lots, places of transportation (e.g., subway platforms), places of business, or from within a vehicle. Individuals exposing themselves from inside a vehicle are more likely to be masturbating. In general, more than half of all exhibitionistic behaviors are thought to involve masturbation. Few cases involve any attempted physical contact with the victim.

Victims of exhibitionistic acts tend to be unknown to the perpetrator and are predominately female. Although few victims report exhibitionistic behavior to police, research by Stephanie Clark and colleagues in 2016 highlights the potential impact of victimization including changes in behavior after exposure (e.g., avoiding being alone) and psychological distress (e.g., feeling scared, shocked, and violated).

Perpetrator Characteristics, Risk of Escalation, and Recidivism

Much of the available research identifying the characteristics of exhibitionists has been conducted on offender samples—that is, perpetrators whose exhibitionistic behaviors have brought them in contact with legal authorities resulting in formal charges or convictions. As a group, these

perpetrators are typically male, with a mean age between 25 and 35 years (although problematic behaviors typically began in adolescence), a history of substance misuse, difficulties with impulse control, and general criminal involvement. Early research also identified problems in interpersonal relations (e.g., intimacy deficits, poor social skills) and possible symptoms of mental illness.

While the majority of perpetrators expose themselves to adult females, a minority are sexually aroused by exposing their genitals to pubescent or prepubescent individuals. As such, identifying the *target* of exhibitionistic urges may assist in identifying comorbid paraphilias (e.g., pedophilia). Perpetrators typically have one or two victims per exposure and those who masturbate during the offense have been found to have a greater number of exhibitionism charges.

Philip Firestone and colleagues have conducted some of the few long-term follow-up studies of exhibitionists. In a sample of 280 exhibitionists referred to a university teaching hospital that were followed up, on average, for over 13 years, approximately 39% were charged with or convicted of a further criminal offense. In addition, roughly 31% of the men were charged or convicted for a violent offense and 24% for a sexual offense. Compared with nonrecidivists, sexual recidivists were less educated and scored higher on measures assessing alcohol misuse, psychopathy, and sexual deviance (i.e., pedophilia). Those who recidivated with *hands-on* or contact sexual offenses had a greater number of prior criminal charges than did the *hands-off* or non-contact recidivists.

Law enforcement and mental health professionals may be asked to assess the *dangerousness* of those who engage in exhibitionistic behavior including the likelihood that a noncontact exhibitionistic offender will escalate to contact offending. Based on their critical review of the exhibitionistic behavior literature, published in 2014, Matthew McNally and William Fremouw estimated that 5–10% of exhibitionistic perpetrators escalate to contact offending over an average follow-up period of approximately 5 years. In this review of 12 peer-reviewed studies, a history of antisocial behavior or general criminality was found to be the most well supported factor for escalation.

Implications for Assessment, Intervention, and Treatment

Historically, reports of high recidivism rates, large numbers of victims, and poor treatment outcomes relative to other sexual offenders have characterized exhibitionistic offenders. Reinvigorated efforts to explore this relatively understudied subgroup of sexual offenders using modern methods (e.g., standardized forensic assessment tools) have yielded some important findings in recent years while at the same time highlighting the potential heterogeneity of this subgroup and need for further research.

There are research findings to suggest that community treatment programs that focus broadly on the criminogenic, or crime-related, needs of men who exhibit (e.g., emotional, cognitive, and interpersonal needs) evidence greater promise than more restrictive programs with a narrow focus on sexually deviant attitudes and interests. In addition to psychological interventions, medications are sometimes used as an adjunct treatment to assist individuals in regulating highly compulsive behaviors including exhibitionistic acts. However, more high-quality research is needed to elucidate and evaluate specific applications of evidence-informed models (e.g., Risk-Need-Responsivity or RNR) of assessment and treatment to this offender subgroup.

Future Directions

Although the majority of exhibitionists do not engage in contact sexual offenses, offenders who exhibit are at risk of criminal recidivism and may require specialized assessment, intervention, and/or treatment to reduce the risk of harm toward themselves and others. Advances in technology (e.g., social media) may provide additional avenues for exhibitionistic behaviors and pursuits, and in the future, online sexual behavior including *electronic exhibitionism* may warrant exploration by law enforcement, forensic mental health professionals, and researchers alike.

EXPERIMENTAL CRIMINOLOGY, RESEARCH METHODS IN

Experimental criminology refers to research that uses experiments to evaluate the effects of a policy, program, or intervention in criminal justice. As used here, an *experiment* is not to be confused with how this word is typically understood by laypeople to mean “the action of trying something new.” In contrast, when used by experimental criminologists, it has a very specific meaning: It is a study that implements the random assignment of units to experimental (E) or control (C) conditions before the introduction of a program, policy, or intervention. An experiment’s main advantage over other research methods is that it provides the greatest assurance that the results achieved are valid. This entry presents a more detailed understanding of experimental criminology by providing a brief history of the use of experiments in the social sciences, the formation of the new field of experimental criminology, the challenges faced by experimental criminologists, and current trends in this field.

Experimentation Versus Experiment

Searching social science databases for titles containing the word *experiment* results in the appearance of thousands of studies. However, only a miniscule number of these publications refer to the more rigorous definition used by experimental criminologists. For these individuals, an

experiment entails a comparison in which people (or places or things) are randomly assigned to groups. One group receives the intervention (the experimental, or E, group) while the other does not (the control, or C, group).

Random assignment is the cornerstone of an experiment. Where large numbers of persons are used, probability theory asserts that, within the limits of slight statistical variation, the two resulting groups should be equivalent. If the researcher then finds differences between the groups after applying the intervention, it can be safely assumed that these differences are due to the intervention. As such, the randomized controlled trial (RCT) offers three benefits not found when using nonexperimental designs. The first is that it minimizes bias in the selection of the two groups, thereby increasing the likelihood that the groups will be equivalent before the intervention is given. In addition, to the extent that random assignment provides every person an equal chance of being selected into the experimental or control group, it controls for chance variability. In other words, this equal probability of selection method uses chance to control for the influence that chance plays on outcomes. Finally, for a comparison between groups to be fair, the groups must not differ in ways that might affect the outcome prior to the introduction of the intervention under study. Random allocation leads to equivalency of the groups prior to the introduction of the intervention by ensuring the even distribution of factors—both those known and unknown to the researcher—that may be related to the outcome.

As the groups are the same prior to the introduction of the intervention, any changes observed in the groups post-intervention will be attributed to the only difference between the groups—the intervention. This allows a researcher using an RCT to make an unequivocal link between the intervention being studied and the outcome observed, thereby providing the least ambiguous evidence of an intervention’s effectiveness. Given this, it should not be surprising that experimental research is referred to as the *gold standard* in evaluation research, as results from an experimental study are more likely to be an accurate reflection of the intervention’s true effectiveness (what is called *internal validity*) in comparison to other nonexperimental methods.

Although there have not been a lot of experiments conducted in the social sciences, those that are done typically attract a good deal of attention. For instance, the 1984 Minneapolis Experiment studied police response to domestic violence calls and the effect this had on repeat violence. Upon answering a domestic violence call for service, police were randomly assigned to either mediate the situation, separate the couple, or arrest the perpetrator. Findings indicated an arrest, even without a subsequent conviction, had a strong deterrent effect on individuals. These results led to changes in how police departments handled domestic violence incidents throughout the United States, with many departments mandating that their officers arrest when responding to these calls.

Scared Straight is a program that brings delinquents into prison where hardened inmates spend 3 hr attempting to terrify them about prison life so as to *scare them straight*. The program was originally highly lauded, leading to jurisdictions nationwide adopting it. However, later experimental research indicated that it was not only ineffective in reducing these teens' likelihood of reoffending, but worse, it demonstrated harmful effects. That is, those who went through this program were more likely to reoffend when compared to the control group who had not been given this program. While some jurisdictions closed their Scared Straight program, there are still many nationwide that continue to run this program.

Finally, one of the most widely known and cited experiments, the Cambridge Somerville Youth Study, randomly assigned boys who were 10–16 years of age and starting to get in trouble with the law into either a control group or a treatment group. Those in the control group received no additional services from this program. But the boys and their families in the treatment group received case management services to assist them when they faced problems. In addition, the boys received an array of services including counseling, summer camp, tutoring, job training, and referral to specialists when thought necessary. The program ran for 5.5 years. It was assumed that the program had a positive impact on the boys' lives. However, the researcher, Joan McCord, returned 30 years later and was able to find and survey 98% of these men on an array of outcomes.

Results indicated that those who received these services had fared worse (e.g., they were more likely to be convicted of a crime, more likely to be alcoholic, more likely to be divorced, less likely to be steadily employed, less pleased with their lives) than those who were not given the program.

In each of these cases, the use of a quasi-experimental design would not have allowed the researcher to rule out competing explanations for observed differences in the outcomes. Using non-experimental designs means that the groups being compared might have been dissimilar prior to receiving the intervention. To counter this, researchers may use matching or engage in statistical controls in an attempt to make the groups equivalent. Although these methods can improve the study's validity, they are not without problems. To the extent that social scientists have yet to fully explain all the causes of social behaviors, it is always conceivable that other unknown and therefore uncontrolled factors influence the outcome. As such, an examination of posttest results will not be able to disentangle whether differences between the groups were due to the intervention or to differences existing between groups prior to the intervention. It should not be surprising, therefore, that researchers find a consistent and negative relationship between the rigor of the research and the likelihood of (falsely) finding an intervention effective.

In the United States, experimental research has had a relatively short but illustrious history. During World War II, a period when the wrong decision could cost lives and perhaps lead to losing the war, the Department of Defense placed a great deal of faith in experimental research. If the government was unsure about which helmet provided better protection, how long a soldier could continue to be effective in military engagement, or which propaganda technique had the greatest impact, an experiment would be implemented. However, by the end of the 1940s, RCTs were declining in use, possibly due to their failing to find many of the programs they evaluated effective. Experimental research reemerged in the 1960s with the start of the War on Poverty. With this massive investment in social programs to eradicate poverty and solve urban problems, the government wanted to determine whether they delivered on their promised outcomes. The

Department of Defense's scientific approach became, once more, the favored methodology. But interest in using experiments to evaluate social programs came to an end in the 1980s due, once again, to this methodology's failure to find most of these interventions effective.

The Start of Experimental Criminology

In an acceptance speech for the 2008 Stockholm Prize in Criminology, Jonathan Shepherd, a medical researcher, voiced concern that there were not more RCTs in criminal justice given the field's focus on public health. Shepherd noted that the medical field had only begun utilizing experimental research in 1946, but, since that time, cures for many diseases had been found largely due to the use of experimental research. This link between medical and criminological research continued with the advent of the Cochrane Collaboration, whose mission was to conduct and disseminate systematic reviews on the effectiveness of medical treatments to assist policy makers, doctors, and patients when making health-care choices.

In 1999, medical researchers began speaking with social scientists about using a similar infrastructure to provide systematic reviews of research that evaluated interventions used in criminal justice, education, and social work. The Campbell Collaboration grew out of these discussions and, within a year, began providing and disseminating systematic reviews. The impetus for both collaborations was the desire to make high-quality research written in a manner that made it accessible to policy makers, agency personnel, and the public. At the heart of both the Cochrane Collaboration and the Campbell Collaboration is the systematic review of experimental research on a given intervention followed by a meta-analysis. As science is built on cumulative knowledge, systematic reviews conducted for the Campbell Collaboration use stringent methods for collecting studies within a given area. Meta-analysis then integrates the evidence from these studies and provides an easily understandable synopsis of an intervention's effectiveness.

Challenges in Experimental Criminology

Criticisms of experimental research in criminal justice settings typically point to these studies

being expensive, time-consuming, and labor-intensive. However, research indicates that they are not significantly costlier, time-consuming, or more labor-intensive than quasi-experiments. In fact, many of the problems that plague experiments apply equally to quasi-experiments conducted in criminal justice. However, there are some difficulties that are unique to RCTs and need to be addressed as the field matures.

One problem is that it is typically more difficult to get agency support when using an experimental design. RCTs have been used so infrequently in criminal justice settings that agency personnel may view them as too difficult or impractical to implement. In addition, it is not uncommon for individuals to hear the word *experiment* and equate it with the Tuskegee Experiment conducted on poor African American sharecroppers from 1932 through 1972 or the Nazi experiments conducted on innocent Jewish civilians during World War II. But neither of these used an experimental design with random assignment to control and experimental groups; therefore, they would not be implemented by an experimental criminologist.

In addition, agency personnel may view RCTs as arbitrary, capricious, or even unethical, especially when it means that an individual viewed as most in need of treatment is randomly assigned to the control group and therefore does not receive the experimental intervention. This situation leads to two potential problems. The first is that agency personnel facing this situation may subvert the random assignment to provide the intervention to the individual in need. Somewhat related is the problem that some individuals may mistakenly view the refusal to provide an intervention in this situation as unethical or illegal.

In fact, it is neither. Many experimentalists make the point that the aforementioned position rests on the assumption that the program being evaluated is beneficial. However, if the intervention has already been found to be beneficial, then there is no need to evaluate it. Experimental criminologists work only with those interventions that have not been rigorously tested. As already noted, without a rigorous evaluation, there is the risk that authorities may unknowingly be providing, or even mandating, interventions that might be ineffective or even harmful (e.g., Scared Straight, Cambridge Somerville Youth Study). Therefore, the

mandate to do no harm would argue for the need to experimentally test new interventions before they are allowed to be widely implemented.

There is also the question about the legality of using an RCT when conducting criminal justice research. While as of 2018 the U.S. Supreme Court has not heard a case on the constitutionality of using random assignment in such settings, expert opinion indicates that this is not viewed as a denial of either equal protection or due process under the law. Specifically, in 1981, Chief Justice Warren Burger assembled a group of nationally recognized scholars to examine this issue. In the end, the group concluded that experiments should be allowed to continue, though they asked that caution be applied when used. In the same year, the Federal Judicial Center, the research arm of the Supreme Court, developed standards for the use of experimental research. These standards included that (a) the results of the intervention were not already known, (b) there were no alternative methods to scientifically determine an intervention's effectiveness, (c) the results would be used to improve the specific intervention, and (d) the rights of the individuals would be protected throughout the study.

Current Trends in Experimental Criminology

Criminology has been one of the social sciences that has taken the lead in experimental research. The Academy of Experimental Criminology was founded in 1999 to advance experimental research in criminology, provide more visibility for studies using an experimental design, and give experimental researchers recognition for the work they are doing. One method used by the Academy of Experimental Criminology for advancing experimental research is providing mentorship to young scholars pursuing an advanced degree to begin their careers as experimental criminologists. The mentorship is provided by Academy of Experimental Criminology fellows who have experience running experiments and are widely respected in their fields of expertise. In addition, in 2005, the *Journal of Experimental Criminology* was established to provide an outlet for experimental research. Despite its brief existence, it is already considered a top-ranked journal for experimental criminologists to publish in. Finally, in 2009, the

Division of Experimental Criminology was formed within the American Society of Criminology, the professional association for criminologists, demonstrating the widespread acceptance of experimental research in the criminal justice field.

EXTORTION

Extortion is a crime committed in many countries around the world by means of violence against property or persons. There exists, however,

regulatory asymmetry in countries' criminal legislation that hinders both the identification of the offender and the appropriate treatment for the victim. If the extortion is occasional and carried out in a private setting (e.g., a son extorting money from his father to buy drugs), in addition to violating a patrimonial right, it is an action that creates an undeniable wound in the victim's psychological integrity, even a tear in his or her moral identity. This entry explores extortion exercised by mafia crime organizations. It discusses extortion's origins, typologies, character, and mode. A final aspect covers the most common articles in sociological and economic studies of extortion.

Extortion generates extensive social damage that extends beyond the direct and immediate relationship to the victim. Extortion has a silent element and those who endure it often file no complaint. This makes it nearly impossible to quantify the phenomenon in different locations, as it is an offense with a high level of *dark numbers* (i.e., crimes committed but not reported).

Extortion by Mafia Crime Organizations

From an economic point of view, extortion as an illegal activity carried out by mafia criminal organizations that produces disruptive effects on the victim and on the economy in question. It discourages investment and distorts an area's economy, making companies vulnerable. It is often utilized in business relations to eliminate competition, networking with other illegal and lucrative activities and thereby reducing the community's sense of security.

Extortion also has a serial element, constituting an activity that discriminates itself as that of a mafia criminal group from a generic criminal group. If a group of young people, set on committing predatory crimes, robberies, or thefts, intends to avoid criminal marginality (thus creating for itself a *Mafioso* profile), the first activity they carry out is extortion.

Extortion is one of the core strategies that the mafia uses to infiltrate legal markets and the public contract cycle. In mafia home territories, extortion precedes any other kind of illegal activity. It is a mother crime, which then leads to other crimes. New mafia settlement areas follow this pattern

and extortion becomes part of the corollary of illegal activities the mafia utilizes.

From a zemiological point of view, the various kinds of damage and social costs that extortion creates can be studied. Taking part in illegal opportunities, however, is not an attribute of the marginal classes alone. An unconventional, circular perspective is bidirectional and also considers criminality originating from white-collar crimes, such as those committed by local administrators, officials and bureaucrats from public agencies, entrepreneurs, professionals, political staff, and on-duty employees. Mafia organizations are able to offer services for the legal and illegal markets. This double integration generates connections with economic, political, and administrative actors. The relationships that are generated, the advantages, the exchanges, and the business that these different actors produce establish a gray area, intermediate, inhabited by a political, entrepreneurial, administrative class that at best represents itself as dishonest rather than criminal.

Social players in legal markets interact with those of illegal markets, resulting in associations that currently underpin the unmentionability of the connection. The zemiological analysis must include, therefore, not only those who already enjoy their criminal connections but also those who exploit or ally themselves in order to achieve personal gain.

Origin

In addition to having an intrinsic illicit nature and a strong dormant character, extortion feeds on conditions where the interaction is a relevant outcome variable, categorized among the following factors:

- the subjection of the victim
- the ability to blackmail the victim
- a way to carry out said event
- a type of economic sector, the enterprise size, local labor market vulnerabilities
- the strength of workers unions
- the criminal group's local area roots and organizational model
- level of presence and dispersion in areas of illicit economic, criminal, and illegal activities
- the level of local social fabric disintegration

- the effectiveness of prevention policies, security, investigative strategies, and court trial processes/findings
- the associative, organizational, and mobilization skills of victims and local communities, who are stakeholders in their affected rights and in the interests that relate to the common legal good

Leopoldo Franchetti (an Italian politician and economist who lived in the late 1800s and early 1900s) provided historical evidence indicating the origin of extortion activities from Sicily. This extortion was provided as protection services and market governance and carried out by the mafia to favor entrepreneurs. In a famous inquest conducted with Sidney Sonnino, Franchetti's (1876) work, *Political and Administrative Conditions in Sicily*, recounts a cartel created by a mafia group formed of several mill companies in the province of Palermo. Members of the cartel, while maintaining a mutual commitment of noncompetition, created a monopoly so that prices would remain high. Therefore, business owners were assured high profits, minimizing risks in market competition, while mafia members ensured pacts were respected by gaining a percentage of the profit.

The mafia was not immediately an official organization, but it is clear that a number of organized groups were created in Western Sicily from the mid-19th century, taking advantage of an agricultural economy still based in large estates and a weak state presence with limited capacity to ensure adequate protection to subsidiaries' interests and rights. This graft was realized by resorting to an existing behavior model based on the use of violence (dilating expressions later) taking over economic resources. The term *mafiusi*, in fact, meant "bully" and the first written document in which it appears in that period is the comedy *The Vicar of Palermu's Mafiusi* by Giuseppe Rizzotto and Gaspare Mosca, first shown in 1863. If the origin of extortion in Sicily is evidenced by several documents from the postunification (1861) period (in which criminals were described as *camorristi*), it was already seen in Naples in the 16th and 17th centuries. The imposition of a *duty* (a kind of tax introduced by long time offenders in prison) began to spread on everything that would enter the prison destined for other inmates.

In the second quarter of the 19th century, prisons and barbaric penal colonies would prove to be

ideal places for camorra cultural development as well as for learning extortion (*pizzo*) and legitimizing it culturally.

This parasitic practice, which dates back to the oldest roots of the Neapolitan camorra phenomenon, extended to legal activities (e.g., the popular markets, the port, every little transaction) and illegal ones (e.g., smuggling, undercover lotteries, the management of popular games). In 1860, even the police prefect, Filippo De Blasio, stressed that the police had to face an association of perverse men who cut anyone by imposing unjust taxes in exchange for peace.

In 1862, Marc Monnier defined the practice of extortion as a permanent and widespread practice applied to any business or commercial activity. He argued that the actions of camorra organized crime are structurally facilitated by a wide cultural and social lawlessness not only rooted in the populace but also inset in segments of bourgeois life. It is an element that still persists in Campania region. It takes the form of illegal activities, many of which (e.g., smuggling, theft, selling counterfeit goods, prostitution) are practiced by marginal people or groups in order to survive. It is also expressed in terms of collusion, the availability for corruption, and increasing one's own interests.

Extortion, therefore, immediately manifests itself in two separate, but cross-functional, properties. It is a primary form of the illegal accumulation of economic resources, which outlines the difference between organized crime and common crime. In addition, it is an effective strategy in controlling a business or economic sector or even an entire area. If the racket is an activity that aims to provide a service (e.g., protection), extortion does not necessarily reveal itself as such and can maintain its exclusive predatory nature. The original activity of extortion by the camorra and the mafia extended to southern areas, spreading to the 'Ndrangheta in Calabria and the Sacra Corona Unita in Puglia.

Today, extortion is the only permanent criminal activity that has spanned the history of criminal organizations and adapted to changes in Italian society. It has expanded beyond the confines of their traditional home territories to national and international levels, to many criminal organizations or global mafias, who preside over trafficking or oversee preparatory functions for entry into legal markets.

Typologies, Character, and Mode

The submerged character of the crime, and in particular the victims' reluctant collaboration, stands in contrast to the crime itself. The dark number varies between regions as a consequence of some of the aforementioned factors. Also of significant importance is the type of criminal organization, the victims' response (which is never unequivocal), the effectiveness of the criminal investigative regulatory framework, and the intensity/decisiveness of the local police force. The profit gained from crime is used both to deal with the so-called *criminal welfare* (e.g., maintaining families of the affiliated organization, expenses in judicial processes, and affiliated salaries) and as an investment into other criminal activities by criminal organizations (e.g., exploitation, the purchase of drugs, smuggling and illegal trafficking). These goals make extortion a functional means of offense with the aim of achieving other objectives.

The manner in which extortion is expressed varies. Sociological and victimology studies in Italy (and in some other European Union countries) have shown that extortion does not express itself only through its traditional protection of private economic players (as it originally did) but is utilized in different forms and adapts to local economies. It can be traditional *protection money*, imposed on commercial activities, businesses, and all legal and illegal economic sectors as a protection fee. The fee can be monthly, periodic, sporadic, or even a one-time payment required as a percentage (e.g., 3%, 5%) proportionate to the amount of the contract. It can also be multiple extortion (a combination of the *pizzo* and the imposition of products, services, and labor). The *pizzo* can be blanket (the victim pays little but pays all economic players within a selected area) or selective (only a few in proportion to turnover).

Other forms of extortion include:

- *masked* extortion, which is the purchase of goods at low prices by means of a front man or by using free goods or services which belong to the victim;
- *predatory* extortion, which is the imposition of a *pizzo* (protection money) without any kind of compensation;
- *extended* extortion, which involves the payment of altered invoices and the setting up of extrabudgetary funds by the victim that are then transferred to the clan/mafia group;
- *entrepreneurial* extortion, which offers (at favorable prices) services, goods, products, and supplies that the victim currently requires; and
- *purchase extortion*, which is based on a combination of extortion and exploitation as a long-term strategy in acquiring control in a business or company.

Protection racket fulfills two functions. First, it allows a predatory accumulation of economic resources. Second, it allows the exercise of territorial sovereignty. The mafias offering (or sometimes imposing) protection services to entrepreneurs restrict competition and are capable of extralegal enforcement of economic transactions in the markets they penetrate. For entrepreneurs, then, mafias provide business development opportunities.

The wide range in forms of extortion helps to explain why not all mafia or camorra groups utilize all types of extortion (e.g., entrepreneurial extortion and multiple extortion are carried out by more established, submerged organizations that have access to legal markets and have a dense distribution network). Activities expand and the victims' reactions vary. Many victims, for example, are in collusion with criminal groups because they can buy goods and services at affordable prices, profiting themselves at the expense of consumers. They may also create an entrepreneurial cartel with other companies and clans to make gains in the form of monopolizing market segments. Other victims operate in illegal conditions (e.g., by violating labor, tax, social security, or environmental laws) and therefore are vulnerable to blackmail. Economist Thomas Schelling claimed the black and submerged markets provide the infrastructure for the business of the underworld.

Extortion in Legal and Illegal Markets

Sociological studies of extortion introduce and refine the insights of precursors Franchetti and John Landesco, an American sociologist and Chicago Crime Commission consultant who

published *Organized Crime in Chicago* in 1929 (a study of organized crime in Chicago during the era of prohibition). The study claims that, in addition to the Italian mafia, the Italian-American mafia, the triads in Hong Kong, the Russian mafia, and the Japanese yakuza are all organizations that offering extralegal services, especially protection. This approach is known as the property rights theory and considers the specialized mafia organizations in the regulation of business affairs, legal property, and economic rights.

Economic studies consider extortion as a rent-seeking activity. Determined by what Douglass C. North terms “institutional and social order), rent-seeking results from inefficiency of the public administration, limited control or deficit in moral legality by the state, local economies in which private investment is reduced, dominating guidelines of rental rates, and decreasing spending on social protection. This vicious cycle makes normal economic activity vulnerable and strengthens economic activity when there are submerged movements in the black market. It is inconsistent work that hinders and distorts development in an area, multiplying the working poor within the fabric of small working businesses, and appearing right at the beginning of the development of a market resembling an official, legal one.
